

A Geometric Basis for Visualizing Time-Varying Volume Data

Department of Computer Science University of North Carolina at Chapel Hill February 2004

The Challenge

Progress in many areas of science and engineering relies on our ability to analyze vast amounts of four-dimensional (4D) data, which are produced to represent the evolution through time of variables such as temperature, pressure, and flow velocity that are measured or computed on a dense set of sample points in space. We include several small examples of jet streams, combustion processes, and pollution studies; large examples can run to hundreds of gigabytes.

The visual exploration of such data is a fundamental tool for engineers, scientists, and educators. It is a complicated task, however, because the data as produced is large, remote, multi-dimensional, and generally featureless. Visualization is time-consuming, because it entails downloading, extracting, and

The points of the control plane correspond to iso-surfaces for this supersonic jet.

Highlights

- The amount of data from scientific and engineering simulations is so large that the overwhelming percentage of it is never inspected.
- We produce tools that suggest where and when to look to find interesting phenomena in the data, based on what could be called “computational topology.”
- We are working toward a system that allows remote inspection of large simulation data sets.

rendering lower-dimensional subsets.

The Approach

Based on recent and projected results in geometric data structures, we are developing a client/server-based tool for visual analysis of iso-surfaces and cross-sections in remotely-located, time-varying volume data. On the client side, we partition the data display into a 3D viewing volume for iso-surfaces and cross-sections and a 2D control plane in which each point corresponds to a particular iso-surface or cross-section. On the server side, we are developing a new geometric data structure based on an unstructured mesh of 4-simplices to support remote storage and real-time interaction with the data.

In brief, the scenario for operation is the following: The server will take the simulation data; simplify it; and compute the simplicial mesh, and annotations for

A pulsed jet data set, with the number of components on the control plane.

the client's control plane that can guide user exploration of the data. The user will set viewing parameters by selecting points on the control plane, and the server will respond with the data needed to display a cross-section or iso-surface. If the user moves slowly across the control plane, following some feature of interest such as a pressure wave at different times, then the server will simply send updates to the iso-surface. If the user stops, then the server will continue to send updates to progressively refine the accuracy of the client's display. To make this scenario possible, research is required on the server (data representation, simplification, and compression), clients (computation and display of topological and geometric features, progressive refinement), and users (effective control plane annotations, interaction rates) for this system.

We also provide guidance for where and when a user should inspect. For example, the control plane can be colored to indicate global properties of the possible views of the data; we color by number of components in the accompanying pictures. Large numbers of components, corresponding to lighter regions, indicate turbulence or other unstable phenomena in these examples.

Project Leader

Jack Snoeyink, professor

Other Investigators

Peter Lindstrom, Lawrence Livermore National Labs
Valerio Pascucci, Lawrence Livermore National Labs
Jarek Rossignac, professor, Georgia Institute of Technology

Graduate Research Assistants

Ajith Mascarenhas

Research Sponsors

Lawrence Livermore National Labs
 National Science Foundation

Key Words

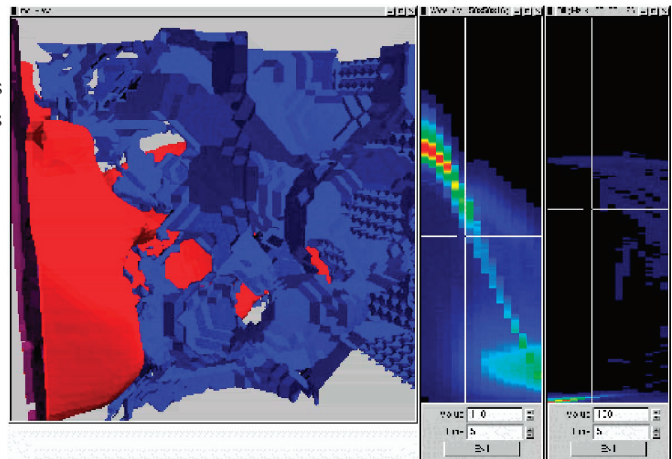

Remote volume visualization; contour tree; computational geometry

Combustion data at different times and density, colored by propagation velocity.
