HIGH-PERFORMANCE PDC
(PARALLEL AND DISTRIBUTED COMPUTING)

Prasun Dewan
Department of Computer Science
University of North Carolina at Chapel Hill
dewan@cs.unc.edu
GOAL

- High Performance PDC (Parallel and Distributed Computing)
  - Important for traditional problems when computers were slow
  - Back to the future with emergence of data science
- Modern popular software abstractions:
  - OpenMP (Parallel Computing and Distributed Shared Memory)
    Late nineties-
  - MapReduce (Distributed Computing) 2004-
  - OpenMPI (~ Sockets, not covered)
- Prins 633 course
  - Covers HPC PDC algorithms and OpenMP in detail.
- Don Smith 590 Course
  - Covers MapReduce uses in detail
- Connect OpenMP and MapReduce to
  - Each other (reduction)
  - Non HPC PDC
  - Research (with which I am familiar)
- Derive the design and implementation of both kinds of abstractions
  - From similar but different performance issues that motivate them.
A TALE OF TWO DISTRIBUTION KINDS

- Remotely Accessible Services (Printers, Desktops)
- Replicated Repositories (Files, Databases)
- Collaborative Applications (Games, Shared Desktops)
- Distributed Sensing (Disaster Prediction)

Differences between the two groups?
**Primary/Secondary Distribution Reason**

- **Primary**
  - Remote Service
  - Fault Tolerance, Availability
  - Collaboration among distributed users
  - Aggregation of Distributed Data
  - High-Performance: Speedup

- **Secondary**
  - Remote service, aggregation,...

- **Remotely Accessible Services (Printers, Desktops)**
- **Replicated Repositories (Files, Databases)**
- **Collaborative Applications (Games, Shared Desktops)**
- **Distributed Sensing (Disaster Prediction)**
- **Computation Distribution (Number, Matrix Multiplication)**
**DIST. VS PARALLEL-DIST. EVOLUTION**

- Remotely Accessible Services (Printers, Desktops)
- Replicated Repositories (Files, Databases)
- Collaborative Applications (Games, Shared Desktops)
- Distributed Sensing (Disaster Prediction)

- Computation Distribution (Number, Matrix Multiplication)

- Distributed Program
- Non-Distributed Existing Program
- Distributed Program
- Non-Distributed Existing Program
- Distributed Program
- Non-Distributed Existing Program
- Distributed Program
- Non-Distributed Existing Program

- Non-Distributed Multi-Thread Program
- Distributed Program
- Distributed Program
- Distributed Program
CONCURRENCY-DISTRIBUTION RELATIONSHIP

- Remotely Accessible Services (Printers, Desktops)
- Replicated Repositories (Files, Databases)
- Collaborative Applications (Games, Shared Desktops)
- Distributed Sensing (Disaster Prediction)

Threads complement blocking IPC primitives by improving responsiveness, removing deadlocks, and allowing certain kinds of distributed applications that would otherwise not be possible.

- e.g. Server waiting for messages from multiple blocking sockets, NIP selector threads sending read data to read thread, creating a separate thread for incoming remote calls

Thread decomposition for speedup and replaced by process decomposition and can be present in decomposed processes.

- e.g. Single-process: each row of matrix A multiplied with column of A by separate thread
- e.g. Multi-process: Each row of matrix assigned to a process, which uses different threads to multiply it with different columns of matrix B.
Algorithmic Challenge

- Remotely Accessible Services (Printers, Desktops)
- Replicated Repositories (Files, Databases)
- Collaborative Applications (Games, Shared Desktops)
- Distributed Sensing (Disaster Prediction)
- Computation Distribution (Number, Matrix Multiplication)

Consistency: How to define and implement correct coupling among distributed processes?

How to parallelize/distribute single-thread algorithms?
**CENTRAL MEDIATOR**

- **Computation Distribution**
  - (Number, Matrix Multiplication)

- **Distributed Sensing**
  - (Disaster Prediction)

- **Collaborative Applications**
  - (Games, Shared Desktops)

- **Replicated Repositories**
  - (Files, Databases)

- **Remotely Accessible Services**
  - (Printers, Desktops)

---

Clients often talk to each through a central server whose code is unaware of specific arbitrary client/slave locations and ports.

A central master process/thread often decomposes problem and combines results computed by slave agents, but decomposer knows about the nature of slaves, which are the service providers.
IMPLEMENTATION CHALLENGE

How to reuse existing single-thread code in multi-thread/multi-process program?

How to add to single-process local observable/observer, producer-consumer and synchronization relationships corresponding distributed observable/observer, producer-consumer and synchronization relationships?

Distributed separation of concerns!

Remotely Accessible Services (Printers, Desktops)

Replicated Repositories (Files, Databases)

Collaborative Applications (Games, Shared Desktops)

Distributed Sensing (Disaster Prediction)

Computation Distribution (Number, Matrix Multiplication)
Communicating threads/processes created independently on typically geographically dispersed autonomous hosts, raising security issues.

Despite crowd problem solving being an infrequent exception: UW Condor – part of Cverse/XSEDE, Wagstaff primes.
Fault Tolerance vs Security

Fault Tolerance

- Byzantine Fault Tolerance
  - Block chain
  - Algorithm Manipulation (Adversary)

- Non-Byzantine Fault Tolerance
  - Two-Phase Commit
  - Paxos

Byzantine and general security problems $\propto$ autonomy

Usually less autonomy in HPC
**Lifetime of Processes/Threads**

- Remotely Accessible Services (Printers, Desktops)
- Replicated Repositories (Files, Databases)
- Collaborative Applications (Games, Shared Desktops)
- Distributed Sensing (Disaster Prediction)

**Long-lived, processes need to be explicitly terminated**

- Computation Distribution (Number, Matrix Multiplication)

**Short-lived, terminate when computation complete**
**Fault Tolerance**

More independent work as goal is to divide common work. Thus faults usually do not propagate. Short-term task can be simply completely or partially restarted.

Faults can be long lived and propagate as goal is to couple processes.

- Remotely Accessible Services (Printers, Desktops)
- Replicated Repositories (Files, Databases)
- Collaborative Applications (Games, Shared Desktops)
- Distributed Sensing (Disaster Prediction)
- Computation Distribution (Number, Matrix Multiplication)
## COUPLING VS HIGH-PERFORMANCE

<table>
<thead>
<tr>
<th>Coupling/Consistency</th>
<th>High Performance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Independent, “long-lived” processes at different autonomous locations made dependent for resource sharing, user collaboration, fault tolerance.</td>
<td>A single short-lived process created to perform some computation made multi-threaded and/or distributed to increase performance.</td>
</tr>
<tr>
<td>Include consistency algorithms, possibly in separate threads, to define dependency that have distributed producer-consumer, observer relationship with existing algorithms</td>
<td>Speedup algorithms that replace logic of existing code, with task decomposition</td>
</tr>
<tr>
<td>May use additional mediating server and other infrastructure code unaware of specific clients.</td>
<td>May involve a central mediating, distributing master code but it can be aware of and creator of specific slave processes</td>
</tr>
<tr>
<td>Division of labor between client and infrastructure an issue (centralized vs replicated)</td>
<td>Division of labor among master and slave and slave and slaves an issue</td>
</tr>
</tbody>
</table>
**Example: Service + Speedup**

![Diagram showing a network of clients, server, and slaves with decomposition levels]

**Assignment-level decomposition**

**Test-level decomposition**

Clients: Client\(^1\), Client\(^2\)

Master and Slave nodes:
- Comp 401 Grader
- Comp 533 Grader
- Tester

Nodes and connections illustrate the distribution of tasks across different levels of decomposition.
Abstractions

- Remotely Accessible Services (Printers, Desktops)
- Distributed Repositories (Files, Databases)
- Collaborative Applications (Games, Shared Desktops)
- Distributed Sensing (Disaster Prediction)
- Computation Distribution (Number, Matrix Multiplication)
- Threads, IPC, Bounded Buffer

Higher-level abstractions for different classes of speedup algorithms?
COMPLETE AUTOMATION?

Remotely Accessible Services (Printers, Desktops)

Distributed Repositories (Files, Databases)

Collaborative Applications (Games, Shared Desktops)

Distributed Sensing (Disaster Prediction)

Modules of Non-Distributed Program Distributed Transparently

Loader contacts registry to determine if local module loaded or remote module accessed

Assumes one name space, one instance of each service – cannot handle replication

Motivates RPC transparency

Parallelizing compilers (Kuck and Kennedy)

Halting problem

Motivates Declarative Abstractions
DECLARATIVE ABSTRACTIONS

- Remotely Accessible Services (Printers, Desktops)
- Distributed Repositories (Files, Databases)
- Collaborative Applications (Games, Shared Desktops)
- Distributed Sensing (Disaster Prediction)
- Computation Distribution (Number, Matrix Multiplication)

- Threads, IPC, Bounded Buffer

- Adding Declarative abstractions for different classes of speedup algorithms
**Declarative vs Imperative: Complementing**

**Declarative: Specify what we want**

```java
floats[] floats = {4.8f, 5.2f, 4.5f};
```

**Imperative: Implement what we want**

```java
public static float sum(Float[] aList) {
    float retVal = (float) 0.0;
    for (int i = 0; i < aList.length; i++) {
        retVal += aList[i];
    }
    return retVal;
}
```

**Type declaration**

4.8  4.8
5.2  5.2
4.5  4.5

**Procedural, Functional, O-O, ...**

**Locality relevant to PDC abstractions - later**

**Loop**
Declarative vs Imperative: Competing

Declarative: Specify what we want

$$\text{(0|1)}^*1$$

Imperative: Implement what we want

FSA (Finite State Automata)

Consistency algorithms are state machines

Ease of programming?
**Declarative vs Imperative PDC: Competing and Complementing**

- **Declarative:** Specify what we want
- **Imperative:** Implement what we want

---

```java
Thread aThread = new Thread(aRunnable);
aThread.start();
```

```java
Server aServer = (Server)
aRegistry.lookup(Server.NAME)
```
Declarative vs Imperative Concurrency: Competing and Complementing

Declarative: Specify what we want

Imperative: Implement what we want

Arguably easier to program.

For restricted classes of programs

Thread aThread = new Thread(aRunnable);
aThread.start();

Concurrency?
**Parallel Random**

0.6455074599676613 0.14361454218773773

Declarative Concurrency Specification Called a Pragma or Directive

```java
//omp parallel threadNum(2)
System.out.println(Math.random());
```

Desired I/O

Declarative Concurrency Aware Code?

Imperative Concurrency-Unaware Code
**OpenMP**

- Language-independent much as RPC and Sockets
- Standard implementations exist for:
  - C/C++
    - #pragma omp parallel num_threads(2)
  - FORTRAN
    - !$OMP PARALLEL NUM_THREADS(2)
- No standard implementation for Java
  - OMP4 implements part of standard (Belohlavek undergrad thesis)
  - //omp parallel threadNum(2)
    - Used in programming examples
- Like Java annotations associated with variable, class and method declarations
  - Associated with statements
- Unified by set of statement attribute values:
  - Parallel (boolean)
  - Number of threads (int)
- Syntax for describing them is similar
- Only certain sets of attributes can be associated with an imperative statement
  - Depends on the kind of statement
# OpenMP Statement Attributes (Abstract)

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Parameters</th>
<th>Semantics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parallel</td>
<td></td>
<td>Create multiple threads to execute attributed statement</td>
</tr>
<tr>
<td>NumberofThreads</td>
<td>int</td>
<td>Number of threads to be created automatically</td>
</tr>
</tbody>
</table>
WHAT PROCESSES THE PRAGMAS?

0.6455074599676613
0.14361454218773773

//omp parallel threadNum(2)
System.out.println(Math.random());

Processed by what kind of program?
PRE-COMPILER APPROACH

Source Program in (Concurrency-Unaware/Aware Native Language + Concurrency-Aware New Language) → New Language Precompiler

Source Program in Concurrency-Aware Native Language → Compiled Program in Concurrency-Aware Imperative Language

Compiled Program in Concurrency-Aware Imperative Language → Native Language Compiler

(Optional) Interpreter

omp4j -s Random.java
javal Random.java
java Random
Imperative Parallel Abstraction?

```java
{  
    int nonStatementNonGlobal = 0;
    //omp parallel threadNum(2)
    {nonStatementNonGlobal++;}
}

Thread.parallel(2,"

System.out.println(Math.random());
");
```

Statement cannot be compiled individually

Parallel method can encapsulate statement in method and class

Interface of class?

Compile errors at runtime

Compilation cost at runtime

Non global (stack) referenced variables outside statement scope and not visible directly to synthesized class

Need (pre) compiler approach!
Java Precompilation of Parallel

```java
{    int nonStatementNonGlobal = 0;
    //omp parallel threadNum(2)
    {nonStatementNonGlobal++;}
}
```

- Attributed statement block encapsulated in Runnable method and Runnable class
- Instead of statement run method of new class instance executed threadNum times
- Parent thread waits for all threads to finish
- Executes next statement

- Creates a context class that has an instance variable for each non-statement and non-global (stack) variable referenced in statement
- Before run method executed non-statement, non-global variables in parent thread stack assigned to corresponding instance variables in context object
- After wait and before next statement instance variables copied back to corresponding statement-non local variables in parent thread stack
Assuming non-stack variables are shared by all threads, so a single context for all threads.
RELATIVE EXPRESSIBILITY OF TWO ABSTRACTIONS

Can $A^1$ implement $A^2$?

- Regular Expressions
- Finite State Automata
- Push Down Automata
- Finite State Automata
- Monitors
- Semaphores
- RMI + Threads
- NIO + Threads

Theory of Computation
- OS: Thread Coordination
- IPC
OTHER CONSIDERATIONS

- Performance
- Ease of Programming (Level)

Usually involves experimental data and arguments rather than proofs
```java
{ int nonStatementNonGlobal = 0;
class OMPContext {
    public int local_nonStatementNonGlobal;
} final OMPContext ompContext = new OMPContext();
ompContext.local_nonStatementNonGlobal = nonStatementNonGlobal;
final org.omp4j.runtime.IOMPExecutor ompExecutor =
    new org.omp4j.runtime.DynamicExecutor(2);
for (int ompI = 0; ompI < 2; ompI++) {
    ompExecutor.execute(new Runnable() {
        @Override
        public void run() {
            {ompContext.local_nonStatementNonGlobal++};
        }
    });
}
ompExecutor.waitForExecution();
nonStatementNonGlobal = ompContext.local_nonStatementNonGlobal;
}
```
MIGRATING FROM C TO JAVA: CASE STUDY

- Pthread_create confused with Unix fork
- Java API and uses looked up
- Thread start() confused with run()
- Long debug time!

- #pragma omp parallel num_threads(2)
- //omp parallel threadNum(2)

Imperative
Declarative
Thread[pool-1-thread-2,5,main] Thread[pool-1-thread-1,5,main] 0.9310973090994396 0.31647362613936514

//omp parallel threadNum(2)
{
    trace(Math.random());
}

public static void trace(Object... anArgs) {
    System.out.print(Thread.currentThread());
    for (Object anArg : anArgs) {
        System.out.print(" "+anArg);
    }
    System.out.println();
}
Java Solution

Desired I/O

Thread[pool-1-thread-2,5,main]
0.6501712957370558
Thread[pool-1-thread-1,5,main]
0.6907459159093547

0.8112103632254872
Thread[pool-1-thread-1,5,main]
0.7339312982272137
Thread[main,5,main] Joined

trace("Forking");

//omp parallel threadNum(2)
{
    //omp critical
    trace(Math.random());
}

trace("Joined");

Serial + Parallel Program

Which thread(s) will print “Forking” and “Joined”? 
Abstract Fork-Join

**T₀** → Statement

**T₀** → Fork(\(n\))

**T₁** → Statement

**Tₙ** → Statement

**T₀** → Join

**T₀** → Statement

- Create thread \(^1\)..thread \(^n\)
- Make each thread execute forked statement
- Make creating thread wait for termination of thread \(^1\)..thread \(^n\)
- More efficient thread creation?
EQUIVALENT, MORE EFFICIENT ABSTRACT FORK-JOIN

$T^0 \rightarrow \text{Statement}$

$T^0 \rightarrow \text{fork(n)}$

$T^0 \rightarrow \text{Statement}$

$T^0 \rightarrow \text{Join}$

$T^0 \rightarrow \text{Statement;}$

- create thread$^1$..thread$^{n-1}$
- Make all thread execute forked statement if it is going to join
- Make creating thread wait for termination of thread$^1$..thread$^{n-1}$
- Implementation requires Statement code to be replicated in both the (in Java, Runnable) code executed by new threads and also in the code execute by the existing thread
- Similar to Unix Fork-Join?
UNIX SINGLE PROCESS FORK-JOIN

- **P0** → Statement
- **childPid = fork()**
- **P0** → Statement
- **P1** → Statement
- **P0** → If (0 != childPid)
- **P1** → join(childPid)
- **P0** → join(childPid)

**System call, returns pid of new process in parent and 0 in child**

**Code executed by both processes**

**Wait for termination of specified child process**

**N-Slaves?**
**Unix Multiple Process Fork-Join**

<table>
<thead>
<tr>
<th>P₀</th>
<th>for (i=1; i &lt; n; i++)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>if (0 != childPid)</td>
</tr>
<tr>
<td>P₀</td>
<td>childPid = fork()</td>
</tr>
<tr>
<td>P₀</td>
<td>Statement</td>
</tr>
<tr>
<td>Pₙ</td>
<td>if (0 != childPid)</td>
</tr>
<tr>
<td>P₀</td>
<td>join()</td>
</tr>
<tr>
<td>P₀</td>
<td></td>
</tr>
</tbody>
</table>

- Procedural (error-prone) code
- Concept of fork-join at least as old as Unix (60s)
- Comparison with OpenMP Parallel Attribute?
- Wait for termination of all child processes

Comparison with OpenMP Parallel Attribute?
SAME CODE/INSTRUCTION, SAME DATA CONCURRENCY

T1

print random#

T2

Same data
SAME CODE/INSTRUCTION, SAME DATA

CONCURRENCY

T1

T2

print “hello world”

Same or No data
Range of Same Code/Instruction, Same Data Concurrency?

System.out.println(isPrime(toInt(Math.random())));
System.out.println("Hello World");

Printing the same value or computing the value is not very useful

Cannot think of other examples

Same data forces some serialization

Range of realistic applications?

Other patterns?
## Parallelization Classes

<table>
<thead>
<tr>
<th></th>
<th>Code/Instruction</th>
<th>Data (Parts)</th>
</tr>
</thead>
<tbody>
<tr>
<td>SISD</td>
<td>Same</td>
<td>Same</td>
</tr>
<tr>
<td>SIMD</td>
<td>Same</td>
<td>Different</td>
</tr>
<tr>
<td>MISD</td>
<td>Different</td>
<td>Same</td>
</tr>
<tr>
<td>MIMD</td>
<td>Different</td>
<td>Different</td>
</tr>
</tbody>
</table>

SISD straightforwardly supported using declarative primitives.

We cannot support all possible concurrencies with pure declarative primitives.
## OpenMP Statement Attributes (Abstract)

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Parameters</th>
<th>Semantics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parallel</td>
<td></td>
<td>Create multiple threads to execute attributed statement, which are killed after execution of statement</td>
</tr>
<tr>
<td>NumberOfThreads</td>
<td>int</td>
<td>Number of threads to be created automatically</td>
</tr>
<tr>
<td>Critical</td>
<td></td>
<td>Make auto-threads execute attributed statement atomically</td>
</tr>
</tbody>
</table>

**Imperative primitives that can be added to these attributes to increase flexibility?**
DIFFERENT CODE, SAME DATA CONCURRENCY

How to integrate alternation with fork-join which requires a single piece of code?

Motivated by Unix?

**UNIX INSPIRATION**

```
for (i=1; i < n; i++)
    If (getPid() != childPid)
    childPid = fork()
    Statement
    If (getPid() != childPid)
    join()
```

Task depends on Id
Allow each member of a thread sequence (declaratively created) execute an imperative step to determine its index.

Different code/data can be executed/accessed by different threads based on their indices.
**ThreadNum Example: Different Code Same Data**

```java
public static void parallelSumAndToText(float[] aList) {
    // omp parallel threadNum(2)
    {
        if (OMP4J_THREAD_NUM == 0) {
            trace("Sum of rounded:" + sum(aList);
        } else {
            trace("ToText of rounded:" + toText(aList));
        }
    }
}
```

OMP4J_THREAD_NUM is a predefined runtime variable with a different value for each forked thread.
## OpenMP Operations and Statement Attributes (Abstract)

<table>
<thead>
<tr>
<th>Attributes</th>
<th>Parameters</th>
<th>Semantics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parallel</td>
<td></td>
<td>Create multiple threads to execute attributed statement, which are killed after execution of statement</td>
</tr>
<tr>
<td>NumberOfThreads</td>
<td>int</td>
<td>Number of threads to be created automatically</td>
</tr>
<tr>
<td>Critical</td>
<td></td>
<td>Make auto-threads execute attributed statement atomically</td>
</tr>
</tbody>
</table>

### Operations

<table>
<thead>
<tr>
<th>Operations</th>
<th>Signature</th>
<th>Semantics</th>
</tr>
</thead>
<tbody>
<tr>
<td>GetThreadNum</td>
<td>( \rightarrow \text{int} )</td>
<td>Returns index of thread created by Parallel pragma</td>
</tr>
<tr>
<td>GetNumThreads</td>
<td>( \rightarrow \text{int} )</td>
<td>Returns number of threads created by Parallel pragma</td>
</tr>
</tbody>
</table>
DIFFERENT CODE, SAME DATA CONCURRENCY

T1 ➔ Code C1 ➔ Same or No data

T2 ➔ Code C2 ➔
SAME CODE, DIFFERENT DATA (PARTS) CONCURRENCY

T1 → Float-List Round → Data (Parts) 1

T2 → Float-List Round → Data (Parts) 2

Need to divide data among threads.
SAME CODE, DIFFERENT DATA (PARTS)

Thread-Aware Float-List Round, Chooses Which Indices to Process Based on ThreadNumber, Number of Threads and Loop Params

What do we need besides thread ID to do the division?
public static void round(float[] aList) {
    trace("Round Started:" + Arrays.toString(aList));
    for (int i = 0; i < aList.length; i++) {
        aList[i] = (float) Math.round(aList[i]);
        trace(aList[i]);
    }
    trace("Round Ended:" + Arrays.toString(aList));
}

ProcessIteration() passed these values and returns Boolean based on whether a thread should process an iteration.
MULTI-THREADED ROUND

```java
public static void parallelRound(float[] aList) {
    // omp parallel threadNum(2)
    {
        trace("Round Started:" + Arrays.toString(aList));
        for (int i = 0; i < aList.length; i++) {
            if (processIteration(i, 0, 1, aList.length,
                                   OMP4J_THREAD_NUM,
                                   OMP4J_NUM_THREADS)) {
                aList[i] = (float) Math.round(aList[i]);
                trace(aList[i]);
            }
        }
        trace("Round Ended:" + Arrays.toString(aList));
    }
}
```
THREAD ASSIGNER

Interface

```java
boolean processIteration(int anIndex, int aStart, int aLimit, int aStepSize, int aThreadNum, int aNumThreads);
```

Different useful implementations of method (possibly chosen by a factory) possible and discussed later

```java
boolean processIteration (int aStart, int aLimit, int aStepSize, int aThreadNum, int aNumThreads) {
    return aNumThreads == 0 ||
        (anIndex % aNumThreads == aThreadNum);
}
```
**Alternate For**

```java
public static void parallelRound(float[] aList) {
    int i = 0;
    // omp parallel threadNum(2)
    for (; ;) {
        if (processIteration(i, 0, aList.length, 1,
            OMP4J_THREAD_NUM, OMP4J_NUM_THREADS)) {

            aList[i] = (float) Math.round(aList[i]);
            trace(aList[i]);
        }
        i++;
        if (i == aList.length)
            break;
    }
}
```

*processIteration()* parameters may not be explicit parameters of for construct

Declarative alternative will not have this property
Two Independent Problems

T1 \rightarrow Float-List Round \rightarrow \text{Step} \rightarrow \text{Step} \rightarrow \text{Step}

T2 \rightarrow Float-List Round \rightarrow \text{Step} \rightarrow \text{Step} \rightarrow \text{Step}

T1 \rightarrow Number-List Sum \rightarrow \text{Step} \rightarrow \text{Step} \rightarrow \text{Step}

T2 \rightarrow Number-List ToString \rightarrow \text{Step} \rightarrow \text{Step} \rightarrow \text{Step}
**Pipelined Functions: Single-Thread**

```java
public static void roundSumAndToText (float[] aList) {
    round(aList);
    trace("Sum of rounded:" + sum(aList);
    trace("ToText of rounded:" + toText(aList));
}
```

Thread[main,5,main] Round Started:[4.8, 5.2, 4.5, 4.75, 4.7]
Thread[main,5,main] Round Ended:[5.0, 5.0, 5.0, 5.0, 5.0]
Thread[main,5,main] Sum of rounded:25.0
Thread[main,5,main] ToText of rounded: 5.0 5.0 5.0 5.0 5.0
Pipelined: Separate Thread Teams

T1 → Float-List Round
T2 → Float-List Round
T3 → Number-List Sum
T4 → Number-List ToString
public static void parallelRound(float[] aList) {

}

    Round Started:[4.8, 5.2, 4.5, 4.75, 4.7]
Thread[pool-1-thread-1,5,main] Round Ended:[5.0, 5.2, 5.0, 4.75, 5.0]
Thread[pool-1-thread-1,5,main] Sum of rounded:24.95
Thread[pool-1-thread-2,5,main] Round Ended:[5.0, 5.0, 5.0, 5.0, 5.0]
Thread[pool-1-thread-2,5,main] ToText of rounded: 5.0 5.0 5.0 5.0 5.0

New declarative construct to fix problem?
public static void parallelRoundAndSumToText(float[] aList) {
    // omp parallel threadNum(2)
    {
        roundWithProcessIteration(aList);
        // omp barrier
        if (OMP4J_THREAD_NUM == 0) {
            trace("Sum of rounded:" + sum(aList));
        } else {
            trace("ToText of rounded:" + toText(aList));
        }
    }
}

Thread[pool-1-thread-1,5/main] Round Started:[4.8, 5.2, 4.5, 4.75, 4.7]
    Round Started:[4.8, 5.2, 4.5, 4.75, 4.7]
Thread[pool-1-thread-2,5/main] Round Ended:[5.0, 5.2, 5.0, 4.75, 5.0]
Thread[pool-1-thread-2,5/main] Round Ended:[5.0, 5.0, 5.0, 5.0, 5.0]
Thread[pool-1-thread-2,5/main] ToText of rounded: 5.0 5.0 5.0 5.0 5.0
Thread[pool-1-thread-1,5/main] Sum of rounded:25.0
## OpenMP Statement Attributes

<table>
<thead>
<tr>
<th>Attributes</th>
<th>Parameters</th>
<th>Semantics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parallel</td>
<td></td>
<td>Create multiple threads to execute attributed statement, which are killed after execution of statement</td>
</tr>
<tr>
<td>NumberOfThreads</td>
<td>int</td>
<td>Number of threads to be created automatically</td>
</tr>
<tr>
<td>Critical</td>
<td></td>
<td>Make auto-threads execute attributed statement atomically</td>
</tr>
<tr>
<td>Barrier</td>
<td></td>
<td>Wait for each sibling created by active Parallel pragma to finish preceding statement before proceeding to next statement</td>
</tr>
</tbody>
</table>

More declarative constructs for patterns we have seen?
Can we get rid of the if - use of imperative constructs in this method?
public static void sectionRoundAndSumToText(float[] aList) {
    // omp parallel threadNum(2)
    {
        roundWithProcessIteration(aList);
        // omp barrier
        // omp sections
        {
            // omp section
            trace("Sum of rounded:" + sum(aList));
            // omp section
            trace("ToText of rounded:" + toText(aList));
        }
    }
}

Sections can be executed in parallel rather than sequentially.
SEQUENTIAL VS CONCURRENT EXECUTION

Begin

T1 → Statement1

T1 → Statement2

T1 → StatementN

End
SEQUENTIAL VS CONCURRENT EXECUTION

CoBegin

T1 → Statement1

T2 → Statement2

T1 → StatementN

CoEnd

A statement/section is executed by a single rather than all threads

Dijsktra (1968)

Co-Begin can replace Begin if no state changes (Functional programming and eager evaluation)
## OpenMP Statement Attributes

</tbody>
</table>
Imperative Thread Assigner

**Interface**

```java
boolean processIteration(int anIndex, int aStart, int aLimit, int aStepSize, int aThreadNum, int aNumThreads);
```

Different useful implementations of method (possibly chosen by a factory) possible and discussed later

```java
Boolean processIteration( int aStart, int aLimit, int aStepSize, int aThreadNum, int aNumThreads) {
    return aNumThreads == 0 ||
    (anIndex % aNumThreads == aThreadNum);
}
```

Suppose the programmer does not care about how iterations are assigned to threads
**Declarative Parallel Round?**

```java
public static void parallelRound(float[] aList) {
    // omp parallel threadNum(2)
    {
        for (int i = 0; i < aList.length; i++) {
            if (processIteration(i, 0, aList.length, 1, OMP4J_THREAD_NUM, OMP4J_NUM_THREADS)) {
                aList[i] = (float) Math.round(aList[i]);
                trace(aList[i]);
            }
        }
    }
}
```

`processIteration()` is problem independent but dependent on loop.
public static void parallelRound(float[] aList) {
    // omp parallel for threadNum(2)
    for (int i = 0; i < aList.length; i++) {
        aList[i] = (float) Math.round(aList[i]);
        trace(aList[i]);
    }
}

Conceptually, OpenMP calls processIteration(), actual implementation does not require each thread to determine if it should execute each iteration.

Allow pragma to be associated with every loop?
Declarative Parallel Round

```java
boolean processIteration(int anIndex, int aStart, int aLimit, int aStepSize, int aThreadNum, int aNumThreads);

public static void parallelRound(float[] aList) {
    int i = 0;
    // omp parallel for threadNum(2)
    for (;;) {
        aList[i] = (float) Math.round(aList[i]);
        trace(aList[i]);
        i++;
        if (i == aList.length)
            break;
    }
}
```

processIteration() cannot be automatically passed loop index and other parameters

OMP for parallelism needs counter-controlled loops: loop with an index variable, increment, start, and limit known at loop entry
## OpenMP Attributes Qualifying Parallel Attributed Loops

SAME CODE, DIFFERENT DATA (PARTS) CONCURRENCY

How should iterations be automatically divided among threads?

Support division parameters set by the programmer
MEMORY ACCESS MODEL

- Data moves from disk to main memory to per-processor cache.
- Disk is larger and slower than main memory which is larger and slower than a cache.
- Main memory is divided into units called pages.
- A cache is divided into units called cache lines or blocks.
- If data accessed by a process is not in main memory, an event called a page fault occurs, which is processed by writing some existing page in main memory to disk and loading the accessed data from disk to the freed saved page.
- Parts of main memory pages accessed by a processor are loaded into cache lines and accessed from cache lines subsequently if they are loaded in cache lines.
- Programs run faster if they have fewer transfers between disk and main memory and main memory and cache.
CACHE CONFLICTS

- Two processors can load cache lines holding the same region of main memory.
- Concurrent writes to cache lines replicating the same memory blocks results in execution of a cache consistency algorithm a la two phase commit and atomic broadcast.
- False sharing occurs from concurrent writes to replicas of the same memory region, and result in unnecessary consistency algorithm executions.
- True sharing occurs from concurrent writes to same words in cache replicas of the same memory block– the overhead of consistency algorithms is necessary now.
- Reading from cache lines does not cause these algorithms to be executed.
- Fewer execution of concurrent consistency algorithms makes program faster.
**Close vs. Far Distance Sharing**

- Far distance sharing can result in threads concurrently accessing different pages, and thus potentially causing more page faults depending on size of memory compared to size of data accessed.

- Close distance sharing can result in more false sharing conflicts as threads access different addresses in cache blocks.

- Moral: Need threads to work with on same pages but not write to overlapping loaded cache lines.

- Reading from overlapping cache lines does not cause any problem.
SAME CODE, DIFFERENT DATA (PARTS) CONCURRENCY

How should iterations be automatically divided among threads?

Support division parameters set by the programmer
### OpenMP Attributes Qualifying Parallel Attributed Loops

### OpenMP Attributes Qualifying Parallel Attributed Loops

<table>
<thead>
<tr>
<th>Attributes</th>
<th>Parameters</th>
<th>Semantics</th>
</tr>
</thead>
<tbody>
<tr>
<td>For</td>
<td></td>
<td>Allow different iterations of a counter-controlled loop to execute in parallel based on properties of counter-controlled loops</td>
</tr>
</tbody>
</table>
| Schedule              | (Static/ Dynamic, int) | Static: All iterations assigned at start of loop  
Dynamic: New iterations assigned dynamically based on progress of previous iterations |
| Step Parameter        | int        | Each thread assigned step number of consecutive iterations (chunk) in static and dynamic                                             |

**Why not always use dynamic?**
**Static vs Dynamic: Variable Iteration Cost**

**Static**
- No load balancing
+ No additional synchronization or context switch overhead after each segment

**Dynamic**
+ Load balancing
- After each segment must check a shared data structure leading to synchronization and possibly context switch (if multiple threads assigned to processor)
**Dynamic (2) Schedule: 3 Threads**

- **T1**: \( I^1, I^2, I^7, I^8 \)
- **T2**: \( I^3, I^4, I^9, I^{10} \)
- **T3**: \( I^5, I^6, I^{11}, I^{12} \)

**Solution:** Smaller step/chunk size?

- Smaller step size leads to better load balancing.
- Larger step size leads to less overhead.
- Variable step size?

**T2 does \( I^{10} \) even though T1 and T3 are free!**
**OpenMP Attributes Qualifying Parallel Attributed Loops**

Grader assignments and tests

Irregular algorithms in general
public static void parallelRound(float[] aList) {
    // omp parallel for threadNum(2) schedule (static, 128)
    for (int i = 0; i < aList.length; i++) {
        aList[i] = (float) Math.round(aList[i]);
        trace(aList[i]);
    }
}
**Parallel Sum?**

```java
public static void parallelSum(float[] aList) {
    float retVal = (float) 0.0;
    // omp parallel for threadNum(2)
    for (int i = 0; i < aList.length; i++) {
        retVal += aList[i];
    }
    return retVal;
}
```

Threads write to common variable
**Parallel Atomic Sum**

```java
public static void parallelSum(float[] aList) {
    float retVal = (float) 0.0;
    // omp parallel for threadNum(2)
    for (int i = 0; i < aList.length; i++) {
        // omp critical
        retVal += aList[i];
    }
    return retVal;
}
```

Computations are serialized!

public static void parallelSum(float[] aList) {
    float retVal = 0.0;
    // omp parallel for threadNum(2)
    for (int i = 0; i < aList.length; i++) {
        // omp critical
        retVal += aList[i];
    }
    return retVal;
}
2-Level Sum Reduction with Parallel For

```java
public static void parallelSum(float[] aList) {
    float retVal = 0.0f;
    float[] aSums = {0.0f, 0.0f};
    // omp parallel for threadNum(2))
    for (int i = 0; i < aList.length; i++) {
        int aThreadNum = 0;
        aSums[OMP4J_THREAD_NUM] += aList[i];
    }
    for (float aSum:aSums) {
        retVal += aSum;
    }
    return retVal;
}
```

Cache issues in allocation of aSums?

False sharing as all threads write to adjacent array slots!
2-Level Sum Reduction with Parallel

```java
public static void parallelSum(float[] aList) {
    float retVal = 0.0f;
    // omp parallel private (aSum)
    {
        float aSum = 0.0f; // private to each thread
        for (int i = 0; i < aList.length; i++) {
            if (processIteration(i, 0, aList.length, 1,
                                  OMP4J_THREAD_NUM,
                                  OMP4J_NUM_THREADS)) {
                aSum += aList[i]; // replaced retVal += aList[i]
            }
        }
        // omp critical
        retVal += aSum; // second reduction
    }
    return retVal;
}
```

2-Level Sum Reduction with Parallel

```java
public static void parallelSum(float[] aList) {
    float retVal = 0.0f;
    // omp parallel private (aSum)
    {
        float aSum = 0.0f; // private to each thread
        for (int i = 0; i < aList.length; i++) {
            if (processIteration(i, 0, aList.length, 1,
                                 OMP4J_THREAD_NUM, OMP4J_NUM_THREADS)) {
                aSum += aList[i]; // replaced retVal += aList[i]
            }
        }
    }
    // omp critical
    retVal += aSum; // second reduction
}
return retVal;
}
```

Can we add more parameters to for parallel to create this automatically?
public static void parallelSum(float[] aList) {
    float retVal = 1.0f;
    // omp parallel private (aSum)
    {
        float aProd = 0.0f; // private to each thread
        for (int i = 0; i < aList.length; i++) {
            if (processIteration(i, 0, aList.length, 1,
                                 OMP4J_THREAD_NUM,
                                 OMP4J_NUM_THREADS)) {
                aProd *= aList[i];
            }
        }
        // omp critical
        retVal *= aProd; // second reduction
    }
    return retVal;
}
public static void parallelSum(float[] aList) {
    float retVal = 0.0;
    // omp parallel for threadNum(2) reduction(+:retVal)
    for (int i = 0; i < aList.length; i++) {
        retVal += aList[i];
    }
    return retVal;
}
PARALLEL WORD COUNT

Words:[the, a, an, the, a]
Counts:{the=2, a=2, an=1}

```java
public static void add (Map<String, Integer> aMap, String aKey, Integer aValue) {
    Integer anOriginalValue = aMap.get(aKey);
    Integer aNewValue = aValue +
        (anOriginalValue == null ? 0 : anOriginalValue);
    aMap.put(aKey, aNewValue);
}

public static Map<String, Integer> wordCount(String[] aWords) {
    Map<String, Integer> aWordCount = new HashMap();
    for (int i = 0; i < aWords.length; i++) {
        add(aWordCount, aWords[i], 1);
    }
    return aWordCount;
}
```

Desired I/O

Integer vs int space issues?
Each Integer addition creates a new object!
Reducible for parallelism?
Both operands of reducible add should be of the same type
PARALLEL WORD COUNT

Words:[the, a, an, the, a]
Counts:{the=2, a=2, an=1

```java
// omp declare reduction
// (mapAdd:java.util.Map<String, Integer>:omp_out=mapPlus(omp_out,omp_in)) 
// initializer(omp_priv= new java.util.HashMap())
public static void mapPlus(Map<String, Integer> aMap,
                            Map<String, Integer> anAddition) {
    for (String aKey:anAddition.keySet()) {
        add(aMap, aKey,anAddition.get(aKey));
    }
}

public static Map<String, Integer> reducableWordCount(String[] aWords) {
    Map<String, Integer> aWordCount = new HashMap();
    // omp parallel for threadNum(aNumThreads) reduction(mapAdd:aWordCount)
    for (int i = 0; i < aWords.length; i++) {
        Map<String, Integer> anAddedValue = new HashMap();
        anAddedValue.put(aWords[i], 1);
        mapPlus(aWordCount, anAddedValue);
    }
    return aWordCount;
}
```
Reduction Method Qualification

// omp declare reduction \
// (<Operation Name>:<Operand Type?::omp_out=<Method>(<omp_out or omp_in>,<omp_out or omp_in)) \ 
// initializer(omp_priv= <Initializing Expression>)

Before the for loop each private variable is assigned <Initializing Expression>

<Operation Name> is used in the for attribute set

The <Method> to which it is bound called after the for

Parameter mp_out is replaced with the for reduction variable and mp_in is replaced with the private variable created from it

- **NumberOfThreads**
  - `Runtime.getRuntime().availableProcessors()`

- **Schedule**
  - Static

- **Step Size**
  - Static
    - Number of iterations/number of threads
    - Each thread gets one chunk
  - Dynamic/Guided
    - 1
HOW MANY THREADS?

P₁ P₂ P₃ P₄

Runtime.getRuntime().availableProcessors()

A¹ T¹¹ T¹² T¹³ T¹⁴

Multiple applications?
MULTIPLE APPLICATIONS

P1  P2  P3  P4

Multi-Process Scheduling Policy?
Common Global Thread Queue

Threads to be made current when time quantum allocated for current threads expires (assuming no blocking)?
FIRST THREAD SWITCH

Does it matter how threads are mapped in the second context switch?
SECOND THREAD SWITCH: PROCESSOR AGNOSTIC

Cache blocks of P1 and P2 may still hold data of $T_{11}$ and $T_{21}$ when they were scheduled last on them.
SECOND CONTEXT SWITCH: PROCESSOR AFFINITY

Affinity-based: Schedule threads on processors on which they were scheduled earlier
Processor Agnostic vs Affinity-Based Scheduling

- Affinity-based can increase performance, *if load does not get unbalanced*, as in our scheme.
- Other scheduling schemes that do affinity based scheduling (Linux) need a load balancing step.
Applications with more threads get more processor time

Reason: Single queue
APPLICATION-AND THREAD-LEVEL QUEUE
Thread Switch
**Application/Process Switch**

- **How to use idle processor?**
  - Threads of next application(s) can use processors not used by current application.

- **Fairness vs throughput?**
  - Allocated time depends on position in application queue.

**Diagram:**

- Application 1: \(A^1\)
- Application 2: \(A^2\)
- Application 3: \(A^3\)
- Threads: \(T^1, T^2, T^3\)
**Single-Level vs Multi-Level Queue**

- **Single-level**
  - Single queue of threads associated with a single time quantum $t$.
  - After $t$ units, thread switch.
  - Applications with more threads get more processor time.

- **Multi-level**
  - Level 1 queue of processes/applications with time quantum $T$
  - Level 2 queue with threads of current application with time quantum $t$.
  - Every $t$ units threads in level-2 queue switched.
  - Every $T$ units processes in level-1 queue switched, which results is new processes' threads to be loaded in second level queue and $n$ threads of next processes’ in level 1 queue if ($n = \# \text{ of processors} - \#\text{threads of current process}) > 0$.
  - The total time a process gets depends on its position in the queue, if it is behind a thread-stingy process, it gets time during its time quantum and also possibly time quantum of processes’ in front of it.

- Can use processor agnostic or affinity based scheduling in both
How to make sure thread always goes to the same processor to make better use of cache?

Divide processors rather than time among applications?
SPACE SCHEDULING
APPLICATIONS < #PROCESSORS
APPLICATION = # PROCESSORS
APPLICATIONS > PROCESSORS

Application wait queue serviced when current applications complete
Space Scheduling

- \#processors - \# applications put in application queue, others in wait queue.
- Processors assigned to active applications with some applications getting more than others if they do not divide evenly.
- An active application continues to use its processors until it completes, when it is replaced with applications in wait queue.
- Threads of an application use time multiplexing to share its applications.
# Space vs. Time Multiplexing

<table>
<thead>
<tr>
<th>Space</th>
<th>Time</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Throughput</strong></td>
<td><strong>Throughput</strong></td>
</tr>
<tr>
<td>- Better use of cache, speedup is sublinear</td>
<td>- Developed when caches were small or non existent</td>
</tr>
<tr>
<td><strong>Response Time</strong></td>
<td><strong>Response times</strong></td>
</tr>
<tr>
<td>- Applications in wait queue must wait until current applications finish</td>
<td>- New small jobs go to front of queue and others go in serviced queue</td>
</tr>
<tr>
<td><strong>Critical mass</strong></td>
<td><strong>Critical mass</strong></td>
</tr>
<tr>
<td>- Certain process teams may not have critical number of processors, producer/consumer, but</td>
<td>- Applications can get critical number of processors</td>
</tr>
</tbody>
</table>
**Uncoordinated Atomicity-Aware Scheduling**

Thread spinning on test and set does no work during its time quantum as thread holding the lock is in the queue.
COORDINATED ATOMICITY-AWARE SCHEDULING

Threads in critical region given more precedence and those spinning given less precedence.
More Coordination: Control Threads?

Should the scheduler and application coordinate on number of threads?

Can an application go faster if it has fewer threads than it can use?

Given N processors, how many threads should be scheduled at one time?

Should the scheduler and application coordinate on number of threads?
**Speedup: Thread vs. Processors**

Why is speedup not linear when there are enough processors?

Thread coordination overhead — cost of splitting and combining work

One active application with n threads or two applications with n/2 processors?

Why does speedup go down when #threads > #processors?

Cache invalidation, lack of coordination, thread switching

Keep # of threads = # processors

---

Figure 1: Speed-up when a matrix multiplication application and an FFT application are run simultaneously and the number of processes per application is varied.

COORDINATED VS UNCOORDINATED ATOMICITY-AWARE SCHEDULING

- **Uncoordinated**
  - Scheduler and application are independent

- **Coordinated scheduling**
  - Application tells scheduler if it is spinning or in critical section.
  - If language/library abstractions support atomicity then they can automatically inform the scheduler which may be implemented by the language/library
COORDINATED VS UNCOORDINATED THREAD-CONTROLLING SCHEDULING

- Uncoordinated
  - Application gets no information about number of threads it should create

- Coordinated
  - The scheduler keeps # of threads = # of processors.
  - Application gets callback about desired number of threads.
  - In dynamic scheduling, it can react to callback by terminating some threads when they finish their current chunk.
  - Moral: dynamic scheduling is better in multi-application computers!

- Two applications running n/2 threads will go faster than one application running n threads as speedup decreases with number of threads
**Dist. vs Parallel-Dist. Evolution**

- **Remotely Accessible Services** (Printers, Desktops)
- **Replicated Repositories** (Files, Databases)
- **Collaborative Applications** (Games, Shared Desktops)
- **Distributed Sensing** (Disaster Prediction)

**Non-Distributed Existing Single-Thread Program**

**Non-Distributed Multi-Thread Program**

**Distributed Program**

**Distributed Sensing** (Disaster Prediction)

**Computation Distribution** (Number, Matrix Multiplication)

**Remote Accessible Services** (Printers, Desktops)

**Replicated Repositories** (Files, Databases)

**Collaborative Applications** (Games, Shared Desktops)

**Distributed Sensing** (Disaster Prediction)
DISTRIBUTED OPENMP ARCHITECTURE
Distributing OpenMP

The Fork-Join model requires input and data to start and end at the for loop one process/thread

Need a software implementation of shared memory

Inconsistent with big data, where all data may not fit in the memory of one process and even if it does, the process becomes a bottleneck.

MapReduce provides a competitor for Fork-Join loop-based reduction (not sections, non-loop parallel, ...
**MapPlus Reduction: Divide and Conquer**

\[ A = \text{mapPlus} (a^1, a^2, a^3 a^4) \]

- **Partial reduction**
  \[ A^1 = \text{mapPlus} (a^1, a^2) \]
  \[ A^2 = \text{mapPlus} (a^3, a^4) \]

- **Final reduction**
  \[ A = \text{mapPlus} (\{(k^1, v^1), (k^2, v^2)\}, (\{(k^1, v^3), (k^1, v^1)\})) \]

Collection result!

Further parallelism when collections are large?
MapPlus Partition: Divide and Conquer

\[ A = \text{mapPlus} (\{(k^1, v^1), (k^2, v^2)\}, \{(k^1, v^3), (k^2, v^4)\}) \]

\[ A^1 = \text{seqPlus} (\{\{(k^1, v^1)\}, \{(k^1, v^3)\}\}) \]

\[ A^2 = \text{seqPlus} (\{\{(k^2, v^2)\}, \{(k^2, v^4)\}\}) \]

\[ A = \text{mapPlus} (A^1, A^2) \]

Values associated with corresponding elements (keys) can be reduced in parallel.
**MapReduce Key Ideas**

- Assume data fits in a set of input files rather than a single process
- Work split to different processes by giving them different portions of the files without first loading them into one process
- Data-based division rather than loop-based division
- Work combined by multiple processes who directly write to output files rather than sending them to one process
**MapReduce Collection-based Division**

- **External Data Structure:** File Text lines
- **In Memory Data Structure:** <Key, Value> pairs (Map)
- **Why Map and not Bean, Array, List, Set?**
  - Can simulate Bean and any collection: array, list, set
  - Values associated with the same keys can be reduced independently as thus in parallel

public class WordCount {
    public static class Map extends MapReduceBase
        implements Mapper<LongWritable, Text, Text, IntWritable> {
        private final static IntWritable one = new IntWritable(1);
        private Text word = new Text();
        public void map(LongWritable key, Text value,
                OutputCollector<Text, IntWritable> output, Reporter reporter)
                throws IOException {
            String line = value.toString();
            StringTokenizer tokenizer = new StringTokenizer(line);
            while (tokenizer.hasMoreTokens()) {
                word.set(tokenizer.nextToken());
                output.collect(word, one);
            }
        }
    }
    Parallelizing/distributing a parameterized method rather than scoped statement
    Infrastructure-provided parameter types and output collection
    Mapper transforms input to reducible output
public static class Reduce extends MapReduceBase
    implements Reducer<Text, IntWritable, Text, IntWritable> {
    public void reduce(Text key, Iterator<IntWritable> values, OutputCollector<Text, IntWritable> output, Reporter reporter)
        throws IOException {
        int sum = 0;
        while (values.hasNext()) {
            sum += values.next().get();
        }
        output.collect(key, new IntWritable(sum));
    }
}

All values associated with a key are automatically collected, reducer is an N-ary method

Output is set of final key, value pairs

Parallelizing/distributing a parameterized method rather than scoped statement

Infrastructure-provided parameter types and output collection
**Map Reduce vs. OpenMP Challenges**

- **OpenMP:** Write problem from scratch and tell OpenMP about parallelization-relevant aspects

- **MapReduce:** Transform problem into a Map and Reduce Method

- Create an FSA for a regular expression

- Convert given expression into another known regular expression using a transformation known to be regular expression preserving

- Proving from scratch the halting problem is intractable

- Reducing known intractable problem into given problem

OpenMP Reduction vs MapReduce Model

OpenMP
- A binary commutative and associative reduce operation known to OpenMP
- A counter-controlled loop known to OpenMP
- Output variable in forking thread known to OpenMP that is an operand to operation on each iteration.
- An expression computed by each loop iteration that is the other operand to operation in iteration.

MapReduce
- An n-ary reduce function that reduces a list of values bound to a key to a single value using an unknown commutative and associative binary function.
- Input text files known to MapReduce
- A map function known to MapReduce that converts each input line to (Key, Value) pairs processed by a reduce function.

</table>
Map/Reduce Functions

- **Mapper Function:**
  - Infrastructure can call map in parallel on different input lines
  - Gets as input a line of text (value parameter) and its offset in the input file (key), which is like the index in a loop
  - Produces as output key-value pairs
  - Each iteration free to determine how input is transformed to output.

- **Reduce Functions:**
  - Infrastructure can call reduce function in parallel with different keys
  - Takes as input a key and a list of map values produced for that key by different map functions, which correspond to local result variables in OpenMP
  - Produces as output a single result reduction value for that key.
**Map Reduce Architecture**

- **Mapper Node and Phase:**
  - Executes in parallel the map function on lines assigned to it.
  - Feeds the output `<keyvalue>` pairs to the local reduce function, as an optional step.
  - Sends each output `<Key, Value>` Pairs produced from map and the optional reduce phase to a reducer that handles it.

- **Reducer Node:**
  - Bound with some target set of keys $K^1$ to $K^n$
  - Different reducers handle different sets of keys
  - Execute the reduce function on data received from remote mappers..
  - Output of this function written to one or more distributed files.
MAP REDUCE INFRASTRUCTURE

- Automation provided based on Map data structure rather than loop
  - Can simulate any collection, bean, or array
- Provides a distributed file system in which different parts of the output can be placed from different locations
- Automatically determines the number and location of mappers and reducers based on input file distribution.
  - Process goes to the data rather than vice versa.
- Automatically splits the input data among the mappers.
- Automatically splits keys (as opposed to iterations) among the reducers.
- Computed results can be combined by multiple reducers
- Reads input data assigned to a mapper and feeds it into a programmer-defined map method.
- Transmits each <Key, Value> output by this method to a local reducer and then a remote reducer that handles it.
- Calls a programmer-defined reduce method in a remote reducer and supplies it with a (key, value) sequence.
- Combines the output of the reduce methods.
Like MapReduce distributes computation among multiple processes and threads without assuming distributes shared memory.

Like MapReduce splits work based on data rather than a loop.

Like OpenMP assumes a single master process is source and sink of input and output data, respectively.

Number of slave threads and processed input is determined through interactive input processed by an MVC architecture.

Uses a bounded buffer of (Key, Value) pairs to distribute work to slave threads of master process a la dynamic scheduling.

A slave thread can delegate work to a free client registered dynamically with the server.
