

COMP 401

METAMORPHOSIS: CASTING VS. CONVERSION

Instructor: Prasun Dewan

PREREQUISITE

- Interfaces
- Types Math
- Deep vs. Shallow Copy (Optional)

METAMORPHOSIS?

```
Point point = new ACartesianPoint (50, 100);  
point = (APolarPoint) point;
```

Class cast exception, Java cast does not automatically convert an instance of a class to an instance of another class

It does not even automatically (deep) copy

Ambiguous semantics

```
Point point = new AMutablePoint (50, 100);  
point = (ABoundedPoint) point;
```

Value of additional properties (upper and lower right corner)?

AS METHODS FOR METAMORPHOSIS

```
public class AConvertibleCartesianPoint
    extends AMutablePoint implements ConvertiblePoint {
    public AConvertibleCartesianPoint(int theX, int theY) {
        super (theX, theY);
    }
    public ConvertiblePoint asCartesianPoint() {
        return this; // could also clone
    }
    public ConvertiblePoint asPolarPoint() {
        return
            new AConvertiblePolarPoint(getRadius(), getAngle());
    }
}
```

```
ConvertiblePoint point =
    new AConvertibleCartesianPoint (50, 100);
point = point.asPolarPoint();
```

Programmer decides what correct conversion means

AUTOMATIC CONVERSION OF PRIMITIVE VALUES

Java cast does not automatically convert an instance of a class to an instance of another class

```
int intVal = 5;  
long longVal = intVal;  
double doubleVal = intVal;  
longVal = Long.MAX_VALUE;  
intVal = (int) longVal;
```

In each of the multi-type assignments, a primitive memory value copied and stored in another primitive memory value of different size

In the last case, cast forces conversion

PRIMITIVE → ANOTHER PRIMITIVE

```
→ int intVal = 5;  
→ long longVal = intVal;  
→ double doubleVal = intVal;  
→ longVal = Long.MAX_VALUE;  
→ intVal = (int) longVal;  
→
```

memory

-1

5

5.0

9223372036
854775807

PRIMITIVE $\leftrightarrow$ OBJECT

```
intVal = (int) longVal;  
Integer integerValue = intVal;  
int intVal2 = integerValue;
```

WRAPPER TYPES

Java automatically converts between primitive and wrapper types when assigning an expression to a variable

MANUAL WRAPPING AND UNWRAPPING

- Integer
 - **public Integer(int value)**
 - **public int intValue()**
- Double
 - **public Double(double value)**
 - **public double doubleValue()**
- Boolean
 - **public Boolean(boolean value)**
 - **public boolean booleanValue()**
- Character
 - **public Character(char value)**
 - **public char charValue()**
- Float, Short, Long

STORAGE OF PRIMITIVES AND WRAPPED VALUES

```
int i = 5
```

```
double d = 5.5
```

```
Integer I = new Integer(i)
```

```
Double D = new Double(d)
```

different sizes

same size

```
int i
```

```
double d
```

```
Integer@8
```

```
Double@16
```

```
Integer I
```

```
Double D
```
