### **Properties of Bezier Curves**

• Invariance under affine parameter transformation

$$\sum_{i=0}^{n} \mathbf{P}_{i} \mathbf{B}_{i,n} (\mathbf{u}) = \sum_{i=0}^{n} \mathbf{P}_{i} \mathbf{B}_{i,n} ((\mathbf{u} - \mathbf{a})/(\mathbf{b} - \mathbf{a}))$$

• Invariance under barycentric combinations (weighted average):

$$\sum_{i=0}^{n} (\alpha \mathbf{Q}_{i} + \beta \mathbf{R}_{i}) \mathbf{B}_{i,n}(\mathbf{u}) = \alpha \sum_{i=0}^{n} \mathbf{Q}_{i} \mathbf{B}_{i,n}(\mathbf{u}) + \beta \sum_{i=0}^{n} \mathbf{R}_{i} \mathbf{B}_{i,n}(\mathbf{u}),$$

$$\alpha + \beta = 1$$

• **Pseudo-local control**:  $B_{i,n}$  (u) has a max at u = i/n. If we move the control point  $P_i$ , then the curve is most affected in the region around the parameter value i/n.

#### **Derivatives of Bezier Curve**

• Derivative of a Bezier curve:

$$\frac{d}{du}\mathbf{P}(\mathbf{u}) = \sum_{0}^{n-1} \Delta \mathbf{P}_{i} B_{i,n-1} (\mathbf{u}) = \mathbf{P}'(\mathbf{u}),$$
where  $\Delta \mathbf{P}_{i} = \mathbf{P}_{i+1}$  -  $\mathbf{P}_{i}$ .

**P'**(u) is also called the *hodograph* curve

- Higher order derivatives can also be defined in terms of lower order Bezier curves
- Based on the derivatives, we can place constraints on the control points for C<sup>1</sup> or G<sup>1</sup> continuity.

# **Degree Elevation**

- Geometric representation of a degree n curve in terms of n+1 degree curve
  - Compute the control points  $(\underline{\mathbf{P}}_i)$  of the elevated curve

$$\sum_{i=0}^{n+1} \mathbf{P}_{i} B_{i,n+1} (\mathbf{u}) = \sum_{i=0}^{n} \mathbf{P}_{i} B_{i,n} (\mathbf{u})$$

where 
$$\underline{\mathbf{P}}_{i} = \left(i/(n+1)\right)\mathbf{P}_{i-1} + \left(1 - i/(n+1)\right)\mathbf{P}_{i}$$
, where  $i=0,\ldots,n+1$ 

• What happens if degree elevation is applied repeatedly?

# Truncating a Bezier Curve

- *Truncation* and subsequent reparametrization: Given a Bezier curve, find the new set of control points of a Bezier curve that define a segment of this curve in the parametric interval:  $u \in [u_i, u_i]$
- Subdivision: Given a Bezier curve, P(u), subdivide at a parameter value  $u_i$ . Compute the control points of two Bezier curves:  $P_1(s)$  and  $P_2(t)$ , so that  $P_1(s)$ , s  $\in [0,1]$  corresponds to P(u), u  $\in [0,1]$ , and  $P_2(t)$ , t  $\in [0,1]$  corresponds to P(u), u  $\in [u_i,1]$ .
- Subdivision can be used to truncate a curve. The control points of the subdivided curve are computed using de Casteljau's algorithm.

# Subdividing a Bezier Curve

- Subdivision doesn't change the shape of a Bezier curve
- It can be used for *local* refinement: subdivide a curve and change the control point(s) of one of the subdivided curve
- The union of convex hulls of the subdivided curve is a subset of the convex hull of the original curve (i.e. the convex hulls are a better approximation of the Bezier curve).
- Asymptotically the control polygons of the subdivided curve converge to the actual curve (at a quadratic rate)
- Subdivision and convex hulls are frequently used for intersection computations
