# Floating-Point Arithmetic

```
if ((A + A) - A == A) {
    SelfDestruct()
}
```

Reading: Study Chapter 3.

What is the problem?

Many numeric applications require numbers over a VERY large range. (*e.g. nanoseconds to centuries*)

Most scientific applications require real numbers (*e.g.* π)

But so far we only have integers.

We *COULD* implement the fractions explicitly (*e.g.* ½, 1023/102934)

We *COULD* use bigger integers

Floating point is a better answer for most applications.

Recall Scientific Notation

- Let's start our discussion of floating point by recalling scientific notation from high school

- Numbers represented in parts:

  Significant Digits
  Exponent

  $$42 = \boxed{4.200} \times 10^{1}$$

  $$1024 = 1.024 \times 10^{3}$$

  $$-0.0625 = -6.250 \times 10^{-2}$$

- Arithmetic is done in pieces

$$
\begin{array}{r}
1024 \\
-\quad 42 \\
\hline
982
\end{array}
$$

$$
\begin{array}{r}
1.024 \times 10^{3} \\
-\ 0.042 \times 10^{3} \\
\hline
0.982 \times 10^{3} \\
\hline
9.820 \times 10^{2}
\end{array}
$$

Before adding, we must match the exponents, effectively "denormalizing" the smaller magnitude number

We then "normalize" the final result so there is one digit to the left of the decimal point and adjust the exponent accordingly.

Multiplication in Scientific Notation

- Is straightforward:
  - Multiply together the significant parts
  - Add the exponents
  - Normalize if required

- Examples:

In multiplication, how far is the most you will ever normalize?

In addition?

1024	1.024	$\times\ 10^3$
$\times\ 0.0625$	6.250	$\times\ 10^{-2}$
64	6.400	$\times\ 10^1$

42	4.200	$\times\ 10^1$
$\times\ 0.0625$	6.250	$\times\ 10^{-2}$
2.625	26.250	$\times\ 10^{-1}$
	2.625	$\times\ 10^0$ (Normalized)

FP == "Binary" Scientific Notation

- IEEE single precision floating-point format

"S" Sign Bit

"E" Exponent + 127

"F" Significand (Mantissa) - 1
0x42280000 in hexadecimal

- Exponent: Unsigned "Bias 127" 8-bit integer

  $$E = \text{Exponent} + 127$$

  Exponent = 10000100 (132) − 127 = 5

- Significand: Unsigned fixed binary point with "hidden-one"

  Significand = "1" + 0.0101000000000000000000000 = 1.3125

- Putting it all together

 $$N = -1^S (1 + F) \times 2^{E-127} = -1^0 (1.3125) \times 2^5 = 42$$

Example Numbers

- One   Sign = +, Exponent = 0, Significand = 1.0

  $-1^0 (1.0) \times 2^0 = 1$

  S = 0, E = 0 + 127, F = 1.0 – '1'

  0 0111111 00000000000000000000000

  0x3f800000

- One-half   Sign = +, Exponent = -1, Significand = 1.0

  $-1^0 (1.0) \times 2^{-1} = \frac{1}{2}$

  S = 0, E = -1 + 127, F = 1.0 – '1'

  0 0111110 00000000000000000000000

  0x3f000000

- Minus Two   Sign = -, Exponent = 1, Significand = 1.0

  1 1000000 00000000000000000000000

  0xc0000000

Zeros

- ## How *do* you represent 0?

- ## Zero   Sign = ?, Exponent = ?, Significand = ?

  - Here's where the hidden "1" comes back to bite you

  - Hint: Zero is small. What's the smallest number you can generate?

  - E = Exponent + 127, Exponent = -127, Signficand = 1.0

    $$1^0 \, (1.0) \times 2^{-127} = 5.87747 \times 10^{-39}$$

- ## IEEE Convention

  - When E = 0 (Exponent = -127), we'll interpret numbers differently...

  $0 \; 00000000 \; 00000000000000000000000 = 0$ not 1.0×2^{-127}

  $1 \; 00000000 \; 00000000000000000000000 = -0$ not -1.0×2^{-127}

  Yes, there are "2" zeros. Setting E=0 is also used to represent a few other small numbers besides 0. In all of these numbers there is no "hidden" one assumed in F, and they are called the "unnormalized numbers". WARNING: If you rely these values you are skating on thin ice!
Infinities

- IEEE floating point also reserves the largest possible exponent to represent "unrepresentable" large numbers

- Positive Infinity – S = 0, E = 255, F = 0

  0 11111111 00000000000000000000000 = +∞

  0x7f800000

- Negative Infinity -- S = 1, E = 255, F = 0

  1 11111111 00000000000000000000000 = -∞

  0xff800000

- Other numbers with E = 255 (F ≠ 0) are used to represent exceptions or Not-A-Number (NAN)

  √-1, -∞ x 42, 0/0, ∞/ ∞, log(-5)

- It does, however, attempt to handle a few special cases:

  1/0 = + ∞, -1/0 = - ∞, log(0) = - ∞

Low-End of the IEEE Spectrum

0 denorm gap 2^{-bias} normal numbers with hidden bit 2^{1-bias} 2^{2-bias}
The gap between 0 and the next representable normalized number is much larger than the gaps between nearby representable numbers.

IEEE standard uses denormalized numbers to fill in the gap, making the distances between numbers near 0 more alike.

0 2^{-bias} 2^{1-bias} 2^{2-bias}

p-1 bits of precision   p bits of precision
Denormalized numbers have a hidden "0" and a fixed exponent of -126

$$X = (-1)^S \ 2^{-126} (0.F)$$

NOTE: Zero is represented using 0 for the exponent and 0 for the mantissa. Either, +0 or -0 can be represented, based on the sign bit.

Floating point AIN'T NATURAL

It is CRUCIAL for computer scientists to know that Floating Point arithmetic is NOT the arithmetic you learned since childhood

1.0 is NOT EQUAL to 10*0.1 (Why?)

    1.0 * 10.0 == 10.0

    0.1 * 10.0 != 1.0

    0.1 decimal == 1/16 + 1/32 + 1/256 + 1/512 + 1/4096 + … ==

        0.0 0011 0011 0011 0011 0011 …

    In decimal 1/3 is a repeating fraction 0.333333…

    If you quit at some fixed number of digits, then 3 * 1/3 != 1

Floating Point arithmetic IS NOT associative

    x + (y + z) is not necessarily equal to (x + y) + z

Addition may not even result in a change

    (x + 1) MAY == x

Floating Point Disasters

- ## Scud Missiles get through, 28 die
    - In 1991, during the 1st Gulf War, a Patriot missile defense system let a Scud get through, hit a barracks, and kill 28 people. The problem was due to a floating-point error when taking the difference of a converted & scaled integer. (Source: Robert Skeel, "Round-off error cripples Patriot Missile", SIAM News, July 1992.)

- ## $7B Rocket crashes (Ariane 5)
    - When the first ESA Ariane 5 was launched on June 4, 1996, it lasted only 39 seconds, then the rocket veered off course and self-destructed. An inertial system, produced an floating-point exception while trying to convert a 64-bit floating-point number to an integer. Ironically, the same code was used in the Ariane 4, but the larger values were never generated (http://www.around.com/ariane.html).

- ## Intel Ships and Denies Bugs
    - In 1994, Intel shipped its first Pentium processors with a floating-point divide bug. The bug was due to bad look-up tables used in to speed up quotient calculations. After months of denials, Intel adopted a no-questions replacement policy, costing $300M. (http://www.intel.com/support/processors/pentium/fdiv/)

Floating-Point Addition
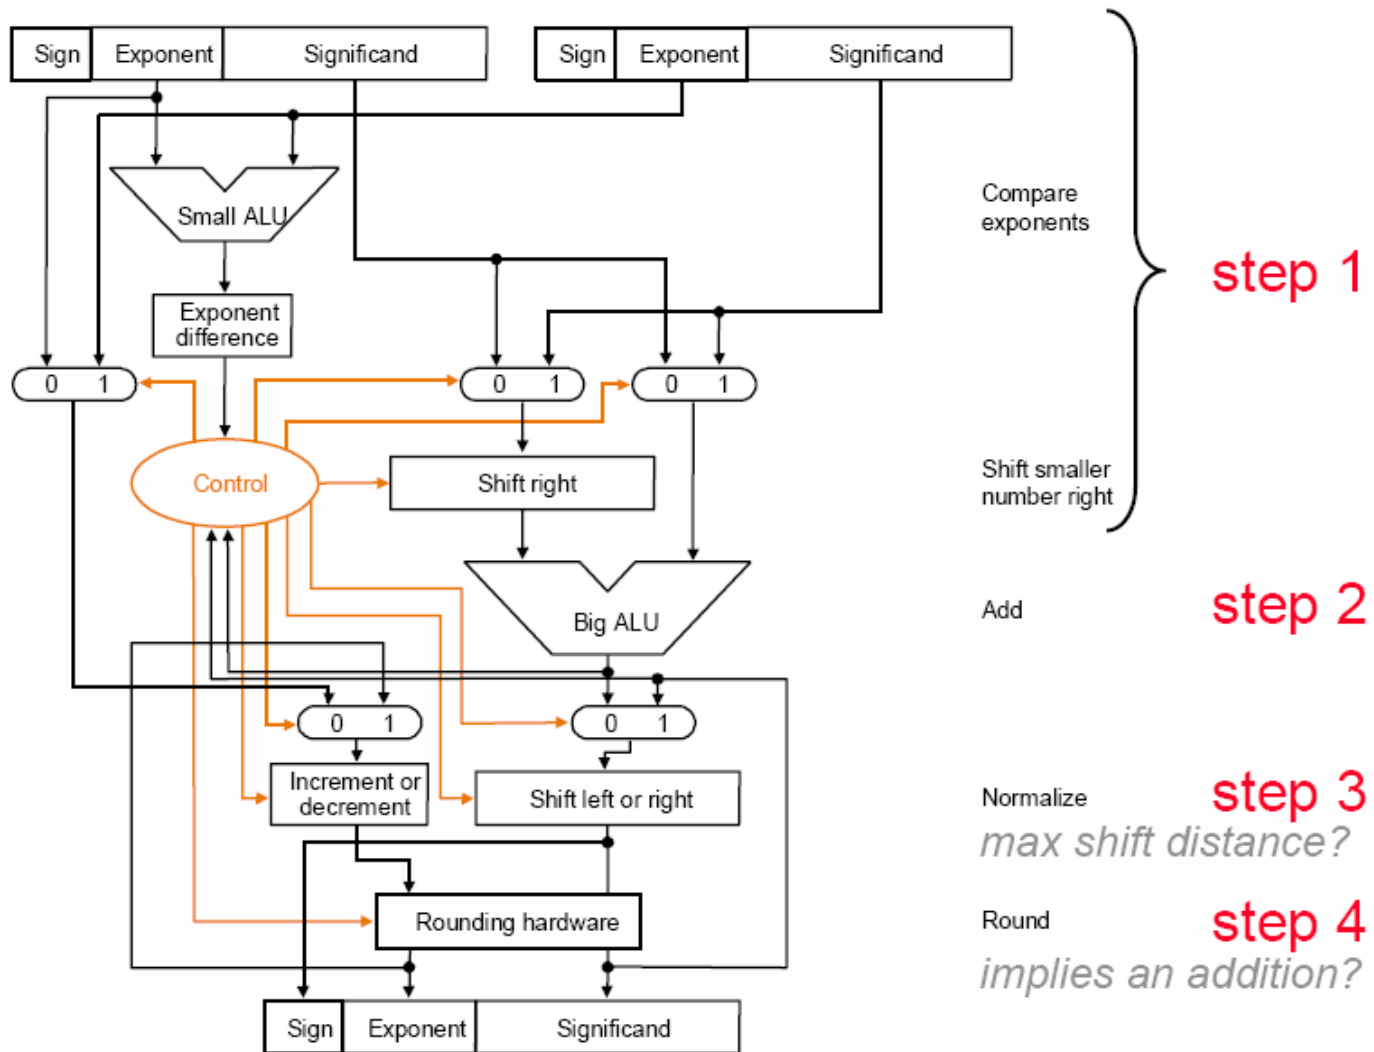

[Figure 3.17 from P&H, COPYRIGHT 2004 Elsevier. ALL RIGHTS RESERVED.]

Floating-Point Multiplication
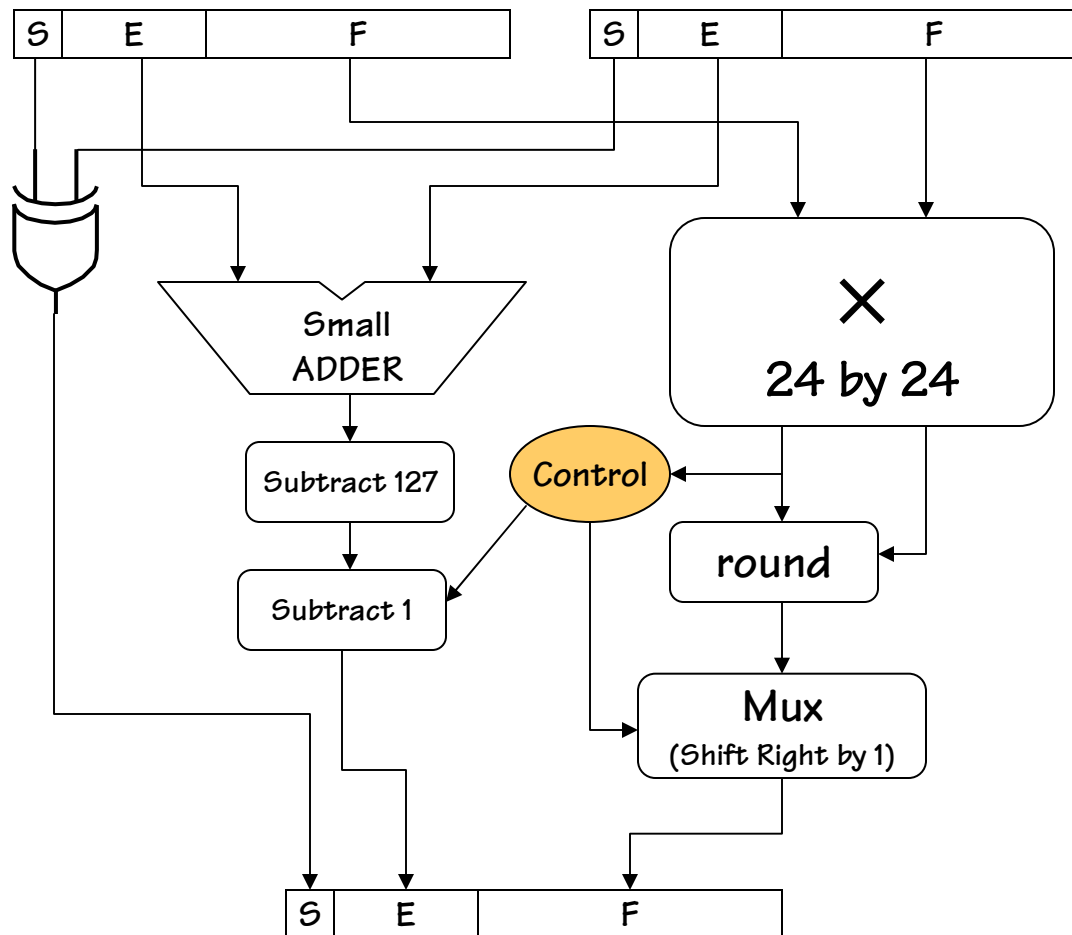

Step 1:

Multiply significands
Add exponents

$E_R = E_1 + E_2 -127$

Exponent$_R$ + 127 =
   Exponent$_1$ + 127
+ Exponent$_2$ + 127
− 127

Step 2:

Normalize result
(Result of
   [1,2) *[1,2) = [1,4)
at most we shift
right one bit, and
fix exponent

Chapter Four Summary

Computer arithmetic is constrained by limited precision

Bit patterns have no inherent meaning but standards do exist

> two's complement

> IEEE 754 floating point

Computer instructions determine "meaning" of the bit patterns

Performance and accuracy are important so there are many complexities in real machines (i.e., algorithms and implementation).

Accurate numerical computing requires methods quite different from those of the math you learned in grade school.
