Lecture 13: Graph Algorithms

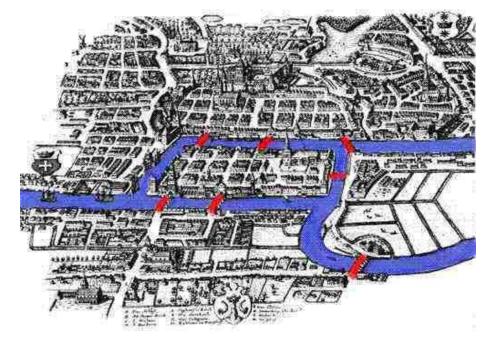

Study Chapter 8.1 – 8.8

10/2/2014

COMP 555 Bioalgorithms (Fall 2014)

The Bridge Obsession Problem

Find a tour crossing every bridge just once *Leonhard Euler, 1735*

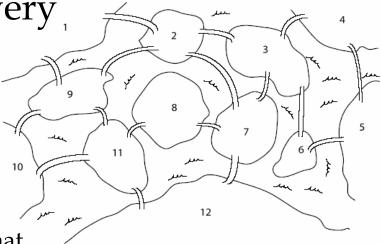

Bridges of Königsberg

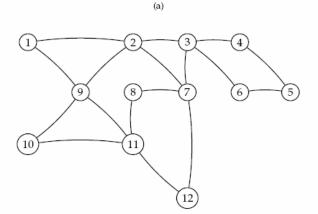

COMP 555 Bioalgorithms (Fall 2014)

Eulerian Cycle Problem

- Find a cycle that visits every edge exactly once
- Linear time
 - Starting at any vertex *v*, and follow a trail of edges until returning to *v*.
 - As long as there exists a vertex *v* that belongs to the current tour, but has adjacent edges not part of the tour, start a new trail from *v*, following unused edges until returning to *v*, and join the tour formed in this way to the previous tour.
 - Special case vertices with odd degree

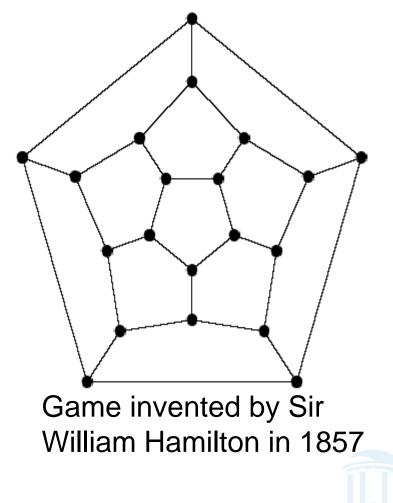

More complicated Königsberg

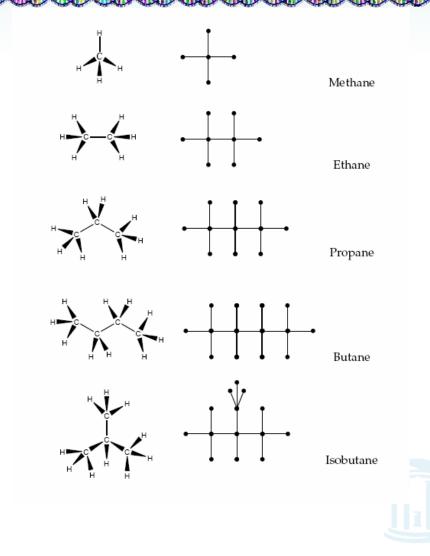

Hamiltonian Cycle Problem

- Find a cycle that visits every *vertex* exactly once
- Deceptively similar to the Eulerian path
- But NP-complete!

Mapping Problems to Graphs

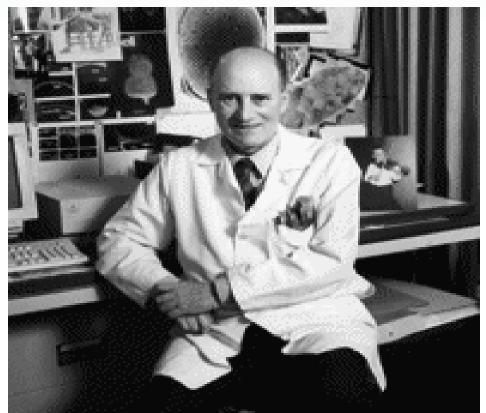

- *Arthur Cayley* studied chemical structures of hydrocarbons in the mid-1800s
- He used **trees** (acyclic connected graphs) to enumerate structural isomers

Beginning of Graph Theory in Biology

Benzer's work

- Developed deletion mapping
- "Proved" linearity of the gene
- Demonstrated internal structure of the gene

Seymour Benzer, 1950s

Viruses Attack Bacteria

- Normally bacteriophage (= virus) T4 kills bacteria
- However if T4 is mutated (e.g., an important gene is deleted) it loses its ability to kill bacteria
- Suppose the bacteria is infected with two different mutants each of which is disabled would the bacteria still survive?
- Amazingly, a pair of disabled viruses can kill a bacteria even if each of them is disabled.
- How can it be explained?

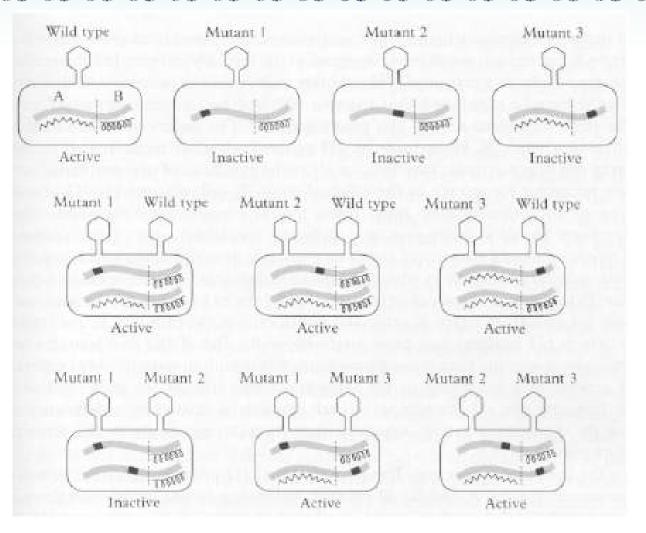

Benzer's Experiment

- Idea: infect bacteria with pairs of mutant T4 viruses
- Each T4 mutant has an unknown interval deleted from its genome
- If the two intervals overlap: T4 pair is missing part of its genome and is disabled bacteria survive
- If the two intervals do not overlap: T4 pair has its entire genome and is enabled bacteria die

Complementary action of mutant T4 bacteriophage pairs

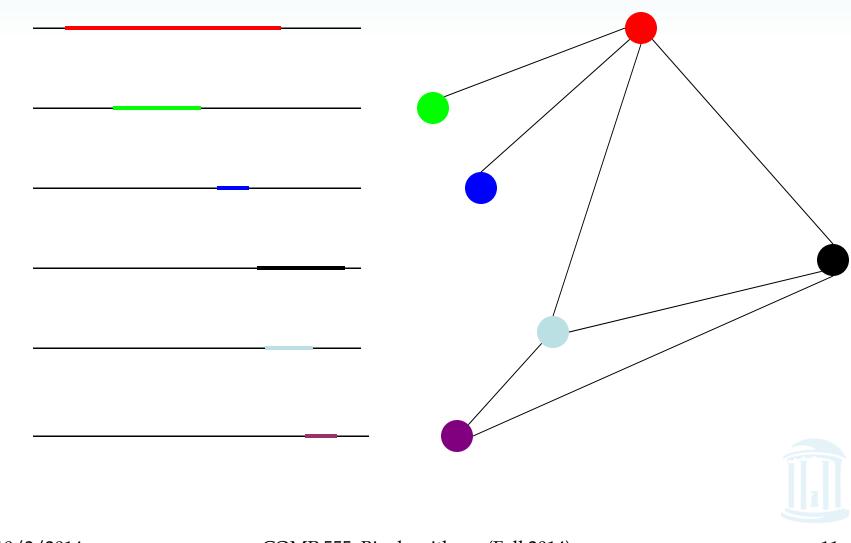

COMP 555 Bioalgorithms (Fall 2014)

Benzer's Experiment and Graphs

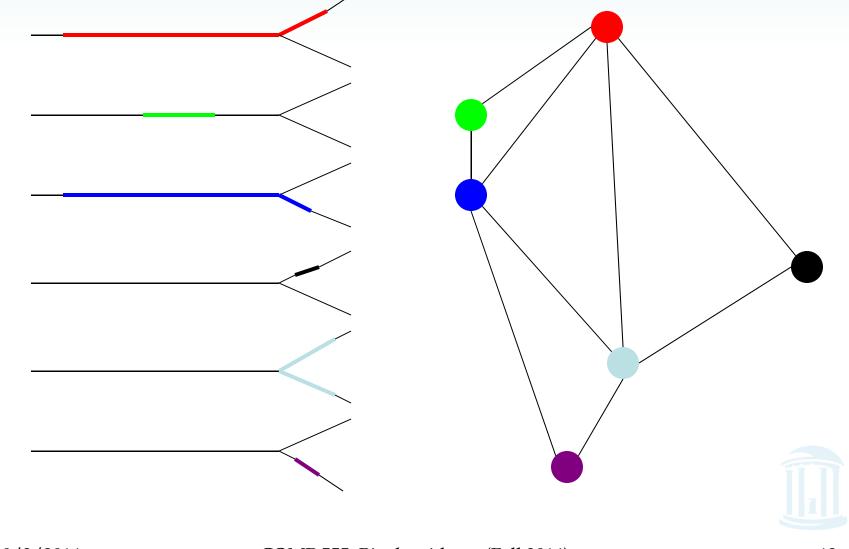

- Construct an **interval graph**: each T4 mutant is a vertex, place an edge between mutant pairs where bacteria survived (i.e., the deleted intervals in the pair of mutants overlap)
- Interval graph structure reveals whether DNA is linear or branched DNA

Interval Graph: Linear Genes

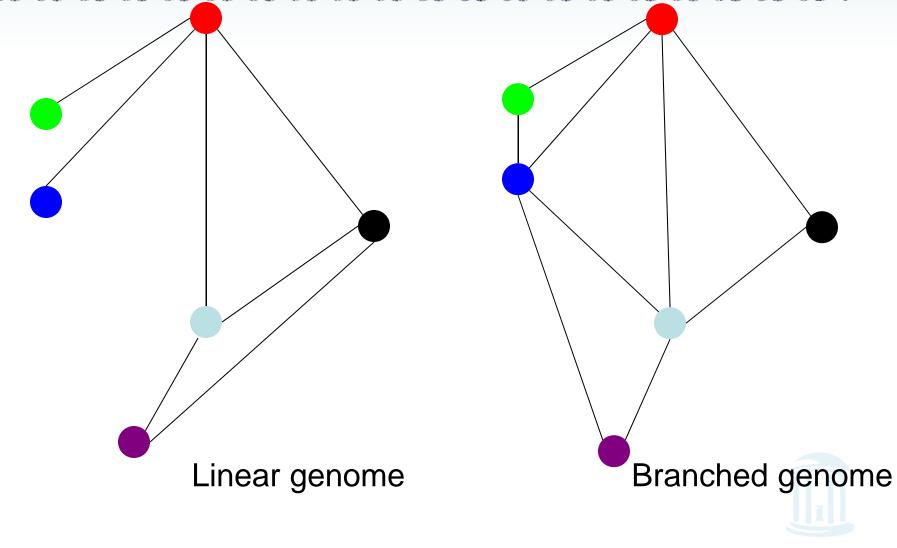

Interval Graph: Branched Genes

COMP 555 Bioalgorithms (Fall 2014)

DNA Sequencing: History

Sanger method (1977): labeled ddNTPs terminate DNA copying at random points.

Gilbert method (1977):

chemical method to cleave DNA at specific points (G, G+A, T+C, C).

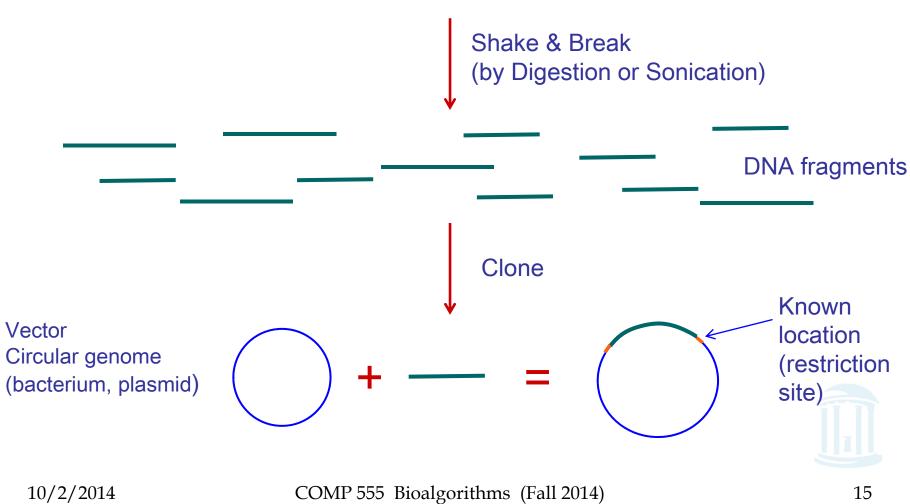

Both methods generate labeled fragments of varying lengths that are further electrophoresed.

ⅆ⅌ⅆⅆⅆⅆⅆⅆ

DNA Sequencing

DNA

Different Types of Vectors

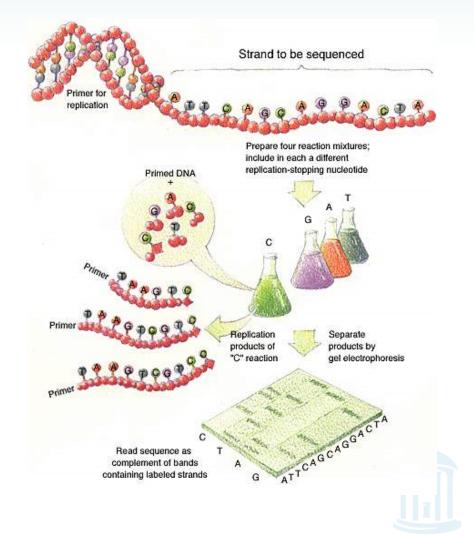

<u>VECTOR</u>	<u>Size of insert (bp)</u>	Insert
Plasmid	2,000 - 10,000	
Cosmid	40,000	
BAC (Bacterial Artificial Chromosome)	70,000 - 300,000	
YAC (Yeast Artificial Chromosome)	> 300,000 Not used much recently	

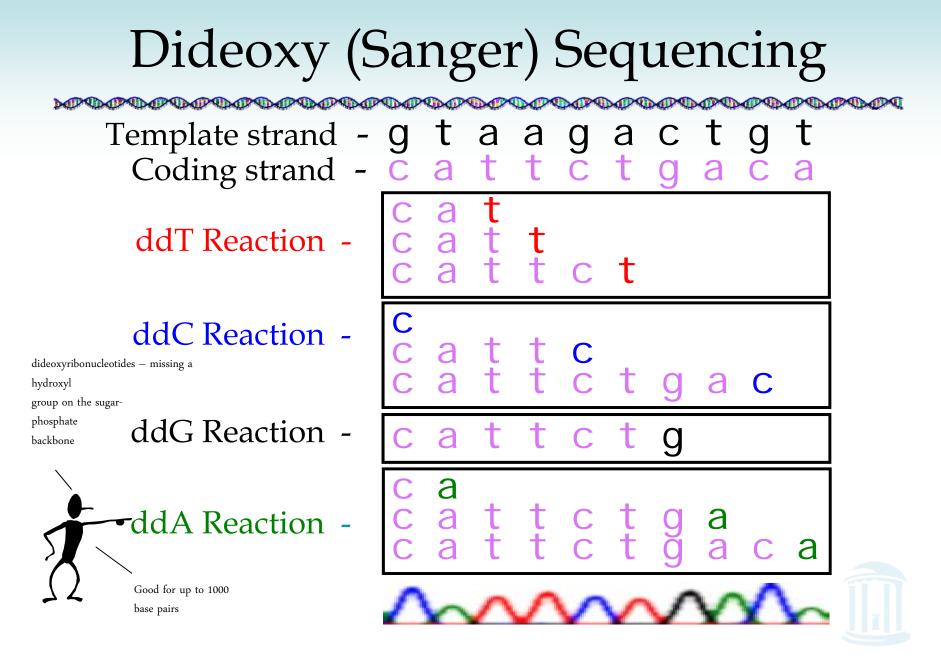

DNA Sequencing

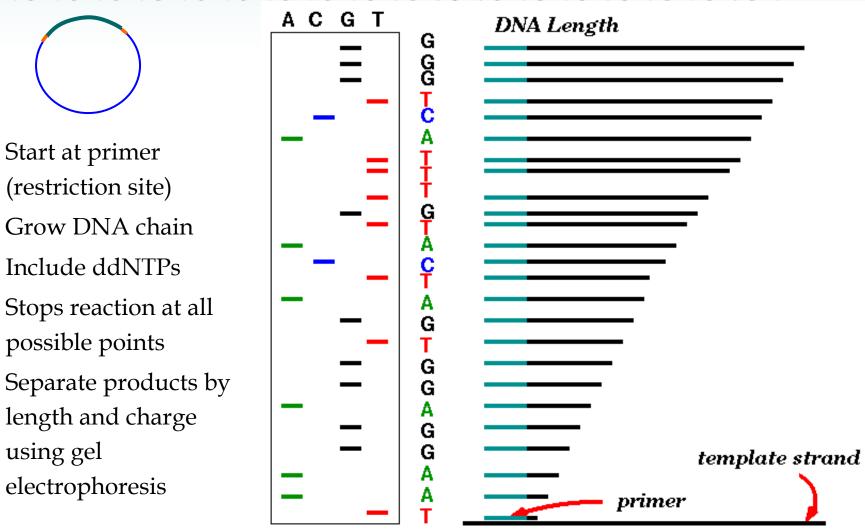

- Shear DNA into millions of small fragments
- Read 500 700

 nucleotides at a time
 from the small
 fragments (Sanger
 method)

Sanger Method: Generating Read

10/2/2014

Reading DNA

- Electrophoresis
 - Sequencing is done by separating subsequences by size (and, in a 2D gel, by size and charge).
 - The DNA molecules are either labeled with radioisotopes or tagged with fluorescent dyes.
 - Given a DNA molecule it is then possible to obtain all fragments from it that end in either A, or T, or G, or C and these can be sorted in a gel experiment.

Fragment Assembly

- <u>Computational Challenge</u>: assemble individual short fragments (reads) into a single genomic sequence ("superstring")
- Until late 1990s the "shotgun" fragment assembly of human genome was viewed as intractable problem

Shortest Superstring Problem

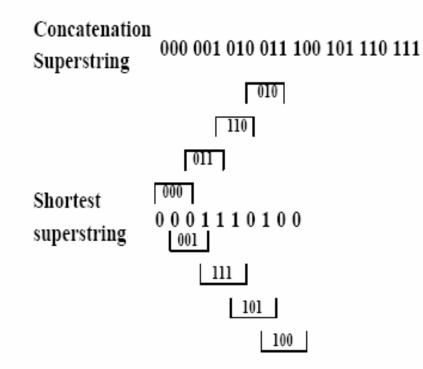

- <u>Problem</u>: Given a set of strings, find a shortest string that contains all of them
- Input: Strings s_1, s_2, \ldots, s_n
- <u>Output</u>: A string *s* that contains all strings
 *s*₁, *s*₂,..., *s*_n as substrings, such that the length of *s* is minimized
- **Complexity:** NP complete
- Note: this formulation does not take into account sequencing errors

Shortest Superstring Problem: Example

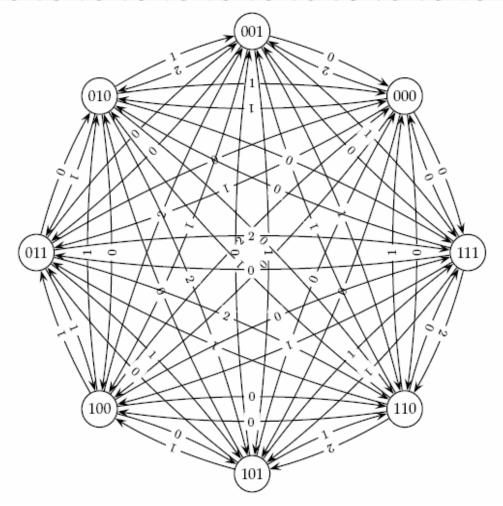

The Shortest Superstring problem

Set of strings: {000, 001, 010, 011, 100, 101, 110, 111}

An overlap graph

COMP 555 Bioalgorithms (Fall 2014)

SSP is NP-complete

• Define *overlap* (*s_i*, *s_j*) as the length of the longest prefix of *s_j* that matches a suffix of *s_i*.

aaaggcatcaaatctaaaggcatcaaa

aaaggcatcaaatctaaaggcatcaaa

What is overlap (s_i, s_j) for these strings?

SSP is NP-complete

• Define *overlap* (*s_i*, *s_j*) as the length of the longest prefix of *s_j* that matches a suffix of *s_i*.

aaaggcatcaaatctaaaggcatcaaa

aaaggcatcaaagctaaaggcatcaaa

overlap=12

SSP is NP-complete

• Define *overlap* (*s_i*, *s_j*) as the length of the longest prefix of *s_j* that matches a suffix of *s_i*.

aaaggcatcaaatctaaaggcatcaaa

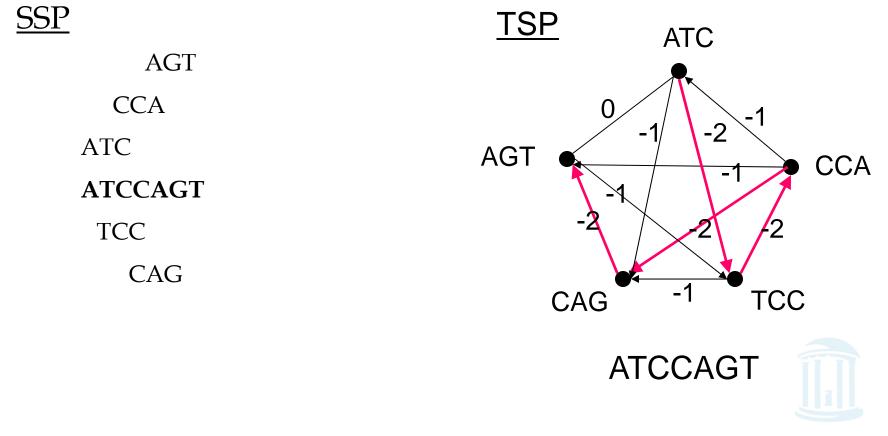

aaaggcatcaaagctaaaggcatcaaa

- Construct a graph with *n* vertices representing the *n* strings *s*₁, *s*₂,..., *s*_n.
- Insert edges of length *-overlap* (s_i , s_j) between vertices s_i and s_j .
- We can find SSP by finding the shortest path (most negative) which visits every vertex exactly once. This is the **Traveling Salesman Problem** (TSP), which is NP–complete.
- Does this prove SSP is NP-complete?
 - No! It shows SSP can be solved using an algorithm that is NP complete, but that doesn't preclude a way to solve it with a lower complexity algorithm.
 - (a proof that SSP is NP-complete is beyond the scope of this course. It shows that TSP can be solved efficiently if there exists an efficient SSP algorithm)

10/2/2014

SSP to TSP: An Example

$S = \{ ATC, CCA, CAG, TCC, AGT \}$

Sequencing by Hybridization (SBH): History

- 1988: SBH suggested as an alternative sequencing method. Nobody believed it will ever work
- **1991:** Light directed polymer synthesis developed by Steve Fodor and colleagues.
- **1994:** Affymetrix develops first 64-kb DNA microarray

First commercial DNA microarray prototype w/16,000 features **(1994)**

500,000 features per chip **(2002)**

How SBH Works

- Attach all possible DNA probes of length *l* to a flat surface, each probe at a distinct and known location. This set of probes is called the DNA array.
- Apply a solution containing fluorescently labeled DNA fragment to the array.
- The DNA fragment hybridizes with those probes that are complementary to substrings of length *l* of the fragment.

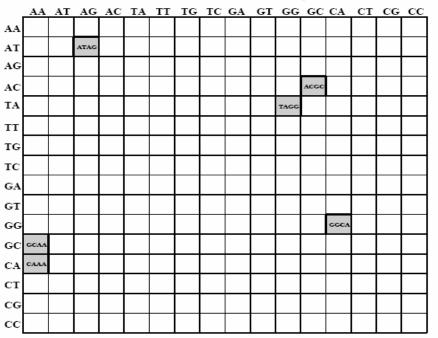

$How \ SBH \ Works \ ({\tt cont'd})$

- Using a spectroscopic detector, determine which probes hybridize to the DNA fragment to obtain the *l*-mer composition of the target DNA fragment.
- We also need to know how many times each *l*-mer is used (must be derived from probe luminescence intensity)
- Apply the combinatorial algorithm (below) to reconstruct the sequence of the target DNA fragment from the *l*-mer composition.

Hybridization on DNA Array

Universal DNA Array

DNA target TATCCGTTT (complement of ATAGGCAAA)

hybridizes to the array of all 4-mers:

ATAGGCAAA ATAG TAGG AGGC GGCA GCAA CAAA

I-mer composition

- *Spectrum* (*s*, *l*) *unordered* multiset of all possible (*n* - *l* + 1) *l*-mers in a string *s* of length *n*
- The order of individual elements in *Spectrum* (*s*, *l*) does not matter
- For s = TATGGTGC all of the following are equivalent representations of Spectrum (s, 3): {TAT, ATG, TGG, GGT, GTG, TGC} {ATG, GGT, GTG, TAT, TGC, TGG} {TGG, TGC, TAT, GTG, GGT, ATG}

I-mer composition

- Spectrum (s, l) unordered multiset of all possible (n - l + 1) l-mers in a string s of length n
- The order of individual elements in *Spectrum* (*s*, *l*) does not matter
- For s = TATGGTGC all of the following are equivalent representations of Spectrum (s, 3): {TAT, ATG, TGG, GGT, GTG, TGC} {ATG, GGT, GTG, TAT, TGC, TGG} {TGG, TGC, TAT, GTG, GGT, ATG}
- We usually choose the lexicographically sorted representation as the canonical one.

Spectrum is not unique

- Different sequences may have the same spectrum:
 - Spectrum(GTATCT,2)= Spectrum(GTCTAT,2)= {AT, CT, GT, TA, TC}

The SBH Problem

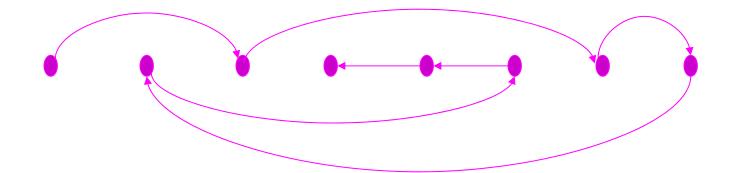

- <u>Goal</u>: Reconstruct a string from its *l*-mer composition
- <u>Input</u>: A set *S*, representing all *l*-mers from an (unknown) string *s*
- <u>Output</u>: String *s* such that Spectrum (s,l) = S

SBH: Hamiltonian Path Approach

$S = \{ ATG AGG TGC TCC GTC GGT GCA CAG \}$

ATG AGG TGC TCC GTC GGT GCA CAG

ATGCAGGTCC

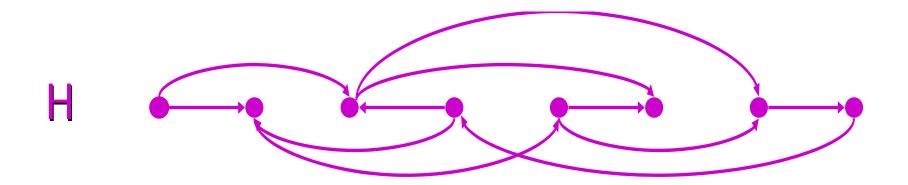

Path visited every VERTEX once

COMP 555 Bioalgorithms (Fall 2014)

SBH: Hamiltonian Path Approach

A more complicated graph:

 $S = \{ ATG TGG TGC GTG GGC GCA GCG CGT \}$

SBH: Hamiltonian Path Approach

 $S = \{ ATG TGG TGC GTG GGC GCA GCG CGT \}$

SBH: Eulerian Path Approach

 $S = \{ATG, TGG, TGC, GTG, GGC, GCA, GCG, CGT \}$

Vertices correspond to (l - 1) – mers : { AT, TG, GC, GG, GT, CA, CG } Edges correspond to l – mers from S

SBH: Eulerian Path Approach

S = { AT, TG, GC, GG, GT, CA, CG } corresponds to two different paths:

COMP 555 Bioalgorithms (Fall 2014)

Euler Theorem

• A graph is balanced if for every vertex the number of incoming edges equals to the number of outgoing edges:

in(v)=out(v)

• **Theorem**: A connected graph is Eulerian if and only if each of its vertices are balanced.

Euler Theorem: Proof

• Eulerian \rightarrow balanced

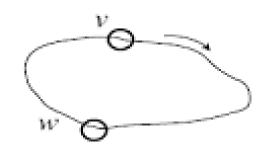

for every edge entering *v* (incoming edge) there exists an edge leaving *v* (outgoing edge). Therefore

$$in(v)=out(v)$$

• Balanced \rightarrow Eulerian ???

Algorithm for Constructing an Eulerian Cycle

a. Start with an arbitrary vertex v and form an arbitrary cycle with unused edges until a dead end is reached. Since the graph is Eulerian this dead end is necessarily the starting point, i.e., vertex v.

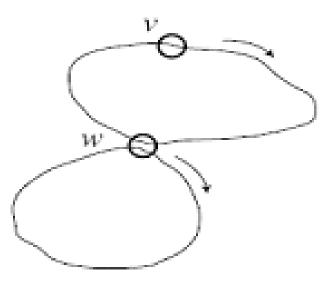

Algorithm for Constructing an Eulerian Cycle (cont'd)

b. If cycle from (a) above is not an Eulerian cycle, it must contain a vertex *w*, which has untraversed edges. Perform step (a) again, using vertex *w* as the starting point. Once again, we will end up in the starting vertex w.

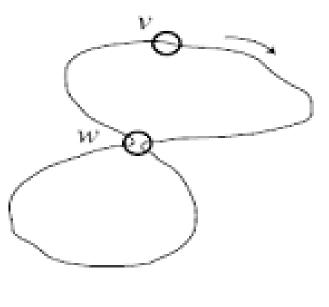

(b)

Algorithm for Constructing an Eulerian Cycle (cont'd)

ⅆ℁ⅆⅆⅆⅆⅆⅆⅆⅆⅆⅆⅆⅆⅆⅆⅆ

c. Combine the cycles
from (a) and (b) into a
single cycle and
iterate step (b).

(c)

Running time: linear to the number of edges

Euler Theorem: Extension

JAPPARAGA

- **Theorem**: A connected graph has an Eulerian path if and only if it contains at most two semi-balanced vertices and all other vertices are balanced.
 - Semi-balanced vertex: in(v) and out(v) differ by 1

Some Difficulties with SBH

- **Fidelity of Hybridization:** difficult to detect differences between probes hybridized with perfect matches and 1 or 2 mismatches
- **Array Size:** Effect of low fidelity can be decreased with longer *l*-mers, but array size increases exponentially in *l*. Array size is limited with current technology.
- **Practicality:** SBH is still impractical. As DNA microarray technology improves, SBH may become practical in the future
- **Practicality again**: Although SBH is still impractical, it spearheaded expression analysis and SNP analysis techniques
