Schedulable Utilization Bounds for EPDF Fair Multiprocessor Scheduling *

UmaMaheswari C. Devi and James H. Anderson

Department of Computer Science, The University of North Carolina, Chapel Hill, NC

Abstract

The earliest-pseudo-deadline-first (EPDF) algorithm is less expensive than other known Pfair algorithms, but is not optimal for scheduling recurrent real-time tasks on more than two processors. Prior work established sufficient per-task weight (i.e., utilization) restrictions that ensure that tasks either do not miss their deadlines or have bounded tardiness when scheduled under EPDF. Implicit in these restrictions is the assumption that total system utilization may equal the total available processing capacity (i.e., the total number of processors). This paper considers an orthogonal issue — that of determining a sufficient restriction on the total utilization of a task set for it to be schedulable under EPDF, assuming that there are no per-task weight restrictions. We prove that a task set with total utilization at most $\frac{3M+1}{4}$ is correctly scheduled under EPDF on $M$ processors, regardless of how large each task’s weight is. At present, we do not know whether this bound is tight. However, we provide a counterexample that shows that it cannot be improved to exceed 86% of the total processing capacity. Our schedulability test is expressed in terms of the maximum weight of any task, and hence, if this value is known, may be used to schedule task sets with total utilization greater than $\frac{3M+1}{4}$.

1 Introduction

We consider the scheduling of recurrent (i.e., periodic, sporadic, or rate-based) real-time task systems on multiprocessor platforms comprised of \( M \) identical, unit-capacity processors. Pfair scheduling, originally introduced by Baruah et al. [8], is the only known way of optimally scheduling such multiprocessor task systems. Under Pfair scheduling, each task must execute at an approximately uniform rate, while respecting a fixed-size allocation quantum. A task’s execution rate is defined by its weight (i.e., utilization). Uniform rates are ensured by subdividing each task into quantum-length subtasks that are subject to intermediate deadlines, called pseudo-deadlines. Subtasks are then scheduled on an earliest-pseudo-deadline-first basis. However, to avoid deadline misses, ties among subtasks with the same deadline must be broken carefully. In fact, tie-breaking rules are of crucial importance when devising optimal Pfair scheduling algorithms.

Srinivasan and Anderson observed that overheads associated with tie-breaking rules may be unnecessary or unacceptable for many soft real-time task systems [16]. A soft real-time task differs from a hard real-time task in that its deadlines may occasionally be missed. If a job (i.e., task instance) or a subtask with a deadline at time \( d \) completes executing at time \( t \), then it is said to have a tardiness of \( \max(0, t - d) \). Overheads associated with tie-breaking rules motivated Srinivasan and Anderson to consider the viability of scheduling soft real-time task systems using the simpler earliest-pseudo-deadline-first (EPDF) Pfair algorithm, which uses no tie-breaking rules. They succeeded in showing that EPDF is optimal on up to two processors [2], and that if each task’s weight is at most \( \frac{q}{q+1} \), then EPDF guarantees a tardiness of at most \( q \) quanta for every subtask [16]. In later work [10], we showed that this condition can be improved to \( \frac{q+1}{q+2} \). If \( M \) denotes the total number of processors, then with either condition, the total utilization of a task set may equal \( M \).

In this paper, we address an orthogonal question: If individual tasks cannot be subject to weight restrictions, then what would be a sufficient restriction on the total utilization of a task set for it to be correctly scheduled under EPDF? We answer this question by providing a sufficient utilization-based schedulability test for EPDF. Such a test is specified by establishing a schedulable utilization bound. If \( U(M) \) is a schedulable utilization bound for scheduling algorithm \( A \), then \( A \) can correctly schedule any set of recurrent tasks with total utilization at most \( U(M) \) on \( M \) processors [12]. If it is also the case that no schedulable utilization bound for \( A \) can exceed \( U(M) \), then \( U(M) \) is an optimal schedulable utilization bound for \( A \).

Schedulability tests can generally be classified as being either utilization-based or demand-based. Though utilization-based tests are usually less accurate than demand-based tests, they can be evaluated in time that is polynomial in the number of tasks. In dynamic systems in which tasks may leave or join at arbitrary times, constant time is sufficient to determine whether a new task may be allowed to join if a utilization-based test is used. On the other hand, demand-based tests require either exponential time, or, at best, pseudo-polynomial time, and hence, when timeliness is a concern, as in online admission-control tests, utilization-based tests are usually preferred. Therefore, devising utilization-based tests is of
considerable value and interest.

Optimal schedulable utilization bounds are known for several scheduling algorithms. In the domain of uniprocessor scheduling, a bound of $1 - 0.01$ is optimal for preemptive earliest-deadline-first (EDF) scheduling, while one of $N(2^{1/N} - 1)$ is optimal for preemptive rate-monotonic (RM) scheduling, where $N$ is the number of tasks [11]. The RM bound converges to $\ln 2 \approx 0.69$ as $N \to \infty$.

Multiprocessor scheduling algorithms use either a partitioned or global scheduling approach. Under partitioning, tasks are assigned to processors by defining a many-to-one mapping (a surjective function) from the set of tasks to the set of processors. Thus, each task is bound to a single processor, and every instance of that task may execute upon that processor only. A separate instance of a uniprocessor scheduling algorithm is then used to schedule the tasks assigned to a processor. If $W_{\text{max}}$, where $0 < W_{\text{max}} \leq 1$, denotes the maximum weight of any task, then a scheduleable utilization bound of $\beta M + 1$ is optimal for the partitioned approach, if EDF is the per-processor scheduling algorithm used [13]. This bound approaches $M + 1$ as $W_{\text{max}} \to 1.0$. Because EDF is an optimal uniprocessor scheduling algorithm, a higher bound is not possible with any other per-processor scheduling algorithm.

Under global scheduling, a task may execute on any processor. This approach can be further differentiated based upon whether a preempted instance is allowed to resume execution on a different processor. If each job is bound to a single processor only, then migrations are said to be restricted; otherwise, they are unrestricted. Under global scheduling, among job-level fixed-priority algorithms, such as EDF, a schedulable utilization bound exceeding $\frac{M+1}{2}$ is impossible, regardless of the nature of migrations [6, 7]. Among static-priority scheduling algorithms, such as RM, a schedulable utilization bound exceeding $\frac{M}{2}$ is impossible for the unrestricted-migrations case [4, 5]. Observe that each of the multiprocessor schedulable utilization bounds considered so far converges to 50% of the total processing capacity.

Pfair scheduling algorithms also fall under the global scheduling category. However, as mentioned earlier, optimal scheduling on multiprocessors is possible with Pfair scheduling. Therefore, each of the optimal Pfair algorithms PF [8], PD [9], and PD$^2$ [15], has an optimal schedulable utilization bound of $M$.

**Contributions.** In this paper, we show that $\frac{(k(k-1)M+1)(k+(k-1)W_{\text{max}})-1}{k(k-1)(1+W_{\text{max}})}$, where $k = \left\lfloor \frac{1}{W_{\text{max}}} \right\rfloor + 1$, is a schedulable utilization bound for the simpler EPDF Pfair scheduling algorithm on $M > 2$ processors.\footnote{EPDF is optimal on up to two processors [3]. Therefore, its optimal schedulable utilization bound on $M \leq 2$ processors is $M$.} For $W_{\text{max}} > \frac{1}{2}$, i.e., $k = 2$, this bound reduces to $\frac{2(M+1)(2+4W_{\text{max}})-1}{4(1+W_{\text{max}})}$, and as $W_{\text{max}} \to 1.0$, it approaches $\frac{3M+1}{4}$, which approaches $\frac{3M}{4}$, i.e., 75% of the total processing capacity, as $M \to \infty$. Note that this bound is greater than that of every known non-Pfair algorithm by 25%.

At present, we do not know if this bound is optimal. However, we provide a counterexample that shows that the bound with $W_{\text{max}} = 1$ cannot exceed 86%. Finally, we extend this bound to allow a tardiness of $q$ quanta.
The rest of the paper is organized as follows. Sec. 2 provides an overview of Pfair scheduling. In Sec. 3, the schedulable utilization bound for EPDF mentioned above is derived. Sec. 4 concludes.

2 Pfair Scheduling

In this section, we summarize relevant Pfair scheduling concepts and state the required definitions and results from [1, 2, 3, 8, 15, 16]. Initially, we limit attention to periodic tasks that begin execution at time 0. Such a task $T$ has an integer period $T.p$, an integer execution cost $T.e$, and a weight $wt(T) = T.e / T.p$, where $0 < wt(T) \leq 1$. A task is light if its weight is less than $1/2$, and heavy, otherwise.

Pfair algorithms allocate processor time in discrete quanta; the time interval $[t, t+1)$, where $t$ is a nonnegative integer, is called slot $t$. (Hence, time $t$ refers to the beginning of slot $t$.) A task may be allocated time on different processors, but not in the same slot (i.e., interprocessor migration is allowed but parallelism is not). The sequence of allocation decisions over time defines a schedule $S$. Formally, $S : \tau \times N \rightarrow \{0, 1\}$, where $\tau$ is a task set and $N$ is the set of nonnegative integers. $S(T, t) = 1$ iff $T$ is scheduled in slot $t$. On $M$ processors, $\sum_{T \in \tau} S(T, t) \leq M$ holds for all $t$.

Lags and subtasks. The notion of a Pfair schedule is defined by comparing such a schedule to an ideal fluid schedule, which allocates $wt(T)$ processor time to task $T$ in each slot. Deviation from the fluid schedule is formally captured by the concept of lag. Formally, the lag of task $T$ at time $t$ is $\text{lag}(T, t) = wt(T) \cdot t - \sum_{u=0}^{t-1} S(T, u)$. (For conciseness, we leave the schedule implicit and use $\text{lag}(T, t)$ instead of $\text{lag}(T, t, S)$.) A schedule is defined to be Pfair iff

$$ (\forall T, t :: -1 < \text{lag}(T, t) < 1). $$

Informally, the allocation error associated with each task must always be less than one quantum.

These lag bounds have the effect of breaking each task $T$ into an infinite sequence of quantum-length subtasks. We denote the $i^{th}$ subtask of task $T$ as $T_i$, where $i \geq 1$. As in [8], we associate a pseudo-release $r(T_i)$ and a pseudo-deadline $d(T_i)$ with each subtask $T_i$, as follows. (For brevity, we often drop the prefix “pseudo-.”)

$$ r(T_i) = \left\lfloor \frac{i-1}{wt(T)} \right\rfloor \quad \text{and} \quad d(T_i) = \left\lceil \frac{i}{wt(T)} \right\rceil $$

(2)

To satisfy (1), $T_i$ must be scheduled in the interval $w(T_i) = [r(T_i), d(T_i))$, termed its window. The length of $T_i$’s window, denoted $|w(T_i)|$, is given by

$$ |w(T_i)| = d(T_i) - r(T_i). $$

(3)

As an example, consider subtask $T_1$ in Fig. 1(a). Here, we have $r(T_1) = 0$, $d(T_1) = 2$, and $|w(T_1)| = 2$. The following lemma relates window lengths and weights.
Figure 1. (a) Windows of the first job of a periodic task $T$ with weight $8/11$. This job consists of subtasks $T_1, \ldots, T_8$, each of which must be scheduled within its window, or else a lag-bound violation will result. (This pattern repeats for every job.) (b) The Pfair windows of an IS task. Subtask $T_5$ becomes eligible one time unit late. (c) The Pfair windows of a GIS task. Subtask $T_3$ is absent and subtask $T_6$ becomes eligible one time unit late.

**Lemma 1** [3] The length of each window of a task $T$ is either $\left\lceil \frac{1}{wt(T)} \right\rceil$ or $\left\lfloor \frac{1}{wt(T)} \right\rfloor + 1$.

Note that, by (2), $r(T_{i+1})$ is either $d(T_i) - 1$ or $d(T_i)$. Thus, consecutive windows either overlap by one slot, or are disjoint. The “$b$-bit,” denoted by $b(T_i)$, distinguishes between these possibilities. Formally,

$$b(T_i) = \left\lceil \frac{i}{wt(T)} \right\rceil - \left\lfloor \frac{i}{wt(T)} \right\rfloor.$$  

(4)

For example, in Fig. 1(a), $b(T_i) = 1$ for $1 \leq i \leq 7$ and $b(T_8) = 0$. We often overload function $S$ (described earlier) and use it to denote the allocation status of subtasks. Thus, $S(T_i, t) = 1$ iff subtask $T_i$ is scheduled in slot $t$.

**Algorithm EPDF.** Most Pfair scheduling algorithms schedule tasks by choosing subtasks to schedule at the beginning of every quantum. As its name suggests, the earliest-pseudo-deadline-first (EPDF) Pfair algorithm gives higher priority to subtasks with earlier deadlines. A tie between subtasks with equal deadlines is broken arbitrarily. As mentioned earlier, EPDF is optimal on at most two processors, but not on an arbitrary number of processors [3].

**Task models.** In this paper, we consider the intra-sporadic (IS) task model and the generalized-intra-sporadic (GIS) task model [2, 15], which provide a general notion of recurrent execution that subsumes that found in the well-studied periodic and sporadic task models. The sporadic model generalizes the periodic model by allowing jobs to be released “late”; the IS model generalizes the sporadic model by allowing subtasks to be released late, as illustrated in Fig. 1(b). More specifically, the separation between $r(T_i)$ and $r(T_{i+1})$ is allowed to be more than $\left\lfloor \frac{i}{wt(T)} \right\rfloor - \left\lfloor \frac{(i-1)}{wt(T)} \right\rfloor$, which would be the separation if $T$ were periodic. Thus, an IS task is obtained by allowing a task’s windows to be shifted right from where they would appear if the task were periodic.

Let $\theta(T_i)$ denote the offset of subtask $T_i$, i.e., the amount by which $w(T_i)$ has been shifted right. Then, by (2), we have the following.

$$r(T_i) = \theta(T_i) + \left\lfloor \frac{i - 1}{wt(T)} \right\rfloor \quad \land \quad d(T_i) = \theta(T_i) + \left\lceil \frac{i}{wt(T)} \right\rceil$$  

(5)
The offsets are constrained so that the separation between any pair of subtask releases is at least the separation between those releases if the task were periodic. Formally,

\[ k > i \Rightarrow \theta(T_k) \geq \theta(T_i). \]  

(6)

Each subtask \( T_i \) has an additional parameter \( e(T_i) \) that specifies the first time slot in which it is eligible to be scheduled. In particular, a subtask can become eligible before its “release” time. It is required that

\[ (\forall i \geq 1 : e(T_i) \leq r(T_i) \land e(T_i) \leq e(T_{i+1})). \]  

(7)

Intervals \( [r(T_i), d(T_i)) \) and \( [e(T_i), d(T_i)) \) are called the PF-window and IS-window of \( T_i \), respectively. A schedule for an IS system is valid iff each subtask is scheduled in its IS-window. (Note that the notion of a job is not mentioned here. For systems in which subtasks are grouped into jobs that are released in sequence, the definition of \( e \) would preclude a subtask from becoming eligible before the beginning of its job.)

\( b \)-bits for IS tasks are defined in the same way as for periodic tasks (refer to (4)). \( r(T_i) \) is defined as follows.

\[ r(T_i) = \begin{cases} 
    e(T_i), & \text{if } i = 1 \\
    \max(e(T_i), d(T_{i-1}) - b(T_{i-1})), & \text{if } i \geq 2 
\end{cases} \]  

(8)

Thus, if \( T_i \) is eligible during \( T_{i-1} \)’s PF-window, then \( r(T_i) = d(T_{i-1}) - b(T_{i-1}) \), and hence, the spacing between \( r(T_{i-1}) \) and \( r(T_i) \) is exactly as in a periodic task system. On the other hand, if \( T_i \) becomes eligible after \( T_{i-1} \)’s PF-window, then \( T_i \)’s PF-window begins when \( T_i \) becomes eligible. Note that (8) implies that consecutive PF-windows of the same task are either disjoint, or overlap by one slot, as in a periodic system.

\( T_i \)’s deadline \( d(T_i) \) is defined to be \( r(T_i) + |w(T_i)| \). PF-window lengths are given by (3), as in periodic systems. Thus, by (5), we have the following.

\[ |w(T_i)| = \left\lfloor \frac{i}{w(T)} \right\rfloor - \left\lfloor \frac{i-1}{w(T)} \right\rfloor \]  

(9)

\[ d(T_i) = r(T_i) + \left\lfloor \frac{i}{w(T)} \right\rfloor - \left\lfloor \frac{i-1}{w(T)} \right\rfloor \]  

(10)

If \( w(T) < 1 \), then \( |w(T_i)| \) is at least two. Therefore, we have the following.

\[ (\forall T : w(T) < 1 : (\forall i \geq 1 : d(T_i) \geq r(T_i) + 2)) \]  

(11)

**Generalized intra-sporadic task systems.** A generalized intra-sporadic task system is obtained by removing subtasks from a corresponding IS task system. Specifically, in a GIS task system, a task \( T \), after releasing subtask \( T_i \), may release subtask \( T_k \), where \( k > i + 1 \), instead of \( T_{i+1} \), with the following restriction: \( r(T_k) - r(T_i) \) is at least \( \left\lfloor \frac{k-1}{w(T)} \right\rfloor - \left\lfloor \frac{i-1}{w(T)} \right\rfloor \).

In other words, \( r(T_k) \) is not smaller than what it would have been if \( T_{i+1}, T_{i+2}, \ldots, T_{k-1} \) were present and released as early
in terms of a function \( f \). Before defining ideal \( T \), let \( \frac{\tau}{T} \) be the lag of \( \frac{T}{T} \) as possible. For the special case where \( T_k \) is the first subtask released by \( T \), \( r(T_k) \) must be at least \( \lfloor \frac{k-1}{\text{wt}(T)} \rfloor \). Fig. 1(c) shows an example. If \( T_i \) is the most recently released subtask of \( T \), then \( T \) may release \( T_k \), where \( k > i \), as its next subtask at time \( t \), if \( r(T_i) + \lfloor \frac{k-1}{\text{wt}(T)} \rfloor - \lfloor \frac{i-1}{\text{wt}(T)} \rfloor \leq t \). If a task \( T \), after executing subtask \( T_i \), releases subtask \( T_k \), then \( T_k \) is called the successor of \( T_i \) and \( T_i \) is called the predecessor of \( T_k \).

As shown in [2], a valid schedule exists for a GIS task set \( \tau \) on \( M \) processors iff

\[
\sum_{T \in \tau} \text{wt}(T) \leq M. \tag{12}
\]

Shares and lags in IS and GIS task systems. The lag of \( T \) at time \( t \) is defined in the same way as for periodic tasks [15]. Let \( \text{ideal}(T, t) \) denote the processor share that \( T \) receives in an ideal fluid (processor-sharing) schedule in \([0, t]\). Then,

\[
\text{lag}(T, t) = \text{ideal}(T, t) - \sum_{u=0}^{t-1} S(T, u). \tag{13}
\]

Before defining \( \text{ideal}(T, t) \), we define \( \text{share}(T, u) \), which is the share assigned to task \( T \) in slot \( u \). \( \text{share}(T, u) \) is defined in terms of a function \( f \) that indicates the share assigned to each subtask in each slot.

\[
f(T_i, u) = \begin{cases} 
\left( \left\lfloor \frac{i-1}{\text{wt}(T)} \right\rfloor + 1 \right) \times \text{wt}(T) - (i - 1), & u = r(T_i) \\
\left( \left\lfloor \frac{i-1}{\text{wt}(T)} \right\rfloor - 1 \right) \times \text{wt}(T), & u = d(T_i) - 1 \\
\text{wt}(T), & r(T_i) < u < d(T_i) - 1 \\
0, & \text{otherwise}
\end{cases} \tag{14}
\]

Fig. 2 shows the values of \( f \) for different subtasks of a task of weight 5/16. Using (14), it is not difficult to see that

\[
(\forall i > 0, u \geq 0 :: f(T_i, u) \leq \text{wt}(T)). \tag{15}
\]

Given \( f \), \( \text{share}(T, u) \) can be defined in terms of \( f \) as

\[
\text{share}(T, u) = \sum_i f(T_i, u). \tag{16}
\]
As shown in Fig. 2(b), \( \text{share}(T, u) \) usually equals \( \text{wt}(T) \), but in certain slots, it may be less than \( \text{wt}(T) \). Also, the total allocation that a subtask \( T_i \) receives in the slots that span its window is exactly one in the ideal system. These and similar properties have been formally proved in [14]. Later in this paper, we will use (17) and (18) given below.

\[
(\forall u \geq 0 :: \text{share}(T, u) \leq \text{wt}(T)) \tag{17}
\]

\[
(\forall T_i :: \sum_{u=r(T_i)}^{d(T_i)-1} f(T_i, u) = 1) \tag{18}
\]

Having defined \( \text{share}(T, u) \), \( \text{ideal}(T, t) \) can then be defined as \( \sum_{u=0}^{t-1} \text{share}(T, u) \). Hence, from (13),

\[
\text{lag}(T, t + 1) = \sum_{u=0}^{t} (\text{share}(T, u) - \text{S}(T, u)) = \text{lag}(T, t) + \text{share}(T, t) - \text{S}(T, t). \tag{19}
\]

The total lag for a task system \( \tau \) with respect to a schedule \( S \) at time \( t \), denoted \( LAG(\tau, t) \) is then given by

\[
LAG(\tau, t) = \sum_{T \in \tau} \text{lag}(T, t). \tag{20}
\]

From (19) and (20), \( LAG(\tau, t + 1) \) can be expressed as follows. (\( LAG(\tau, 0) \) is defined to be 0.)

\[
LAG(\tau, t + 1) = LAG(\tau, t) + \sum_{T \in \tau} (\text{share}(T, t) - \text{S}(T, t)). \tag{21}
\]

The rest of this section presents some additional definitions and results that will be used in the rest of this paper.

**Active tasks.** It is possible for a GIS (or IS) task to have no eligible subtasks and a share of zero during certain time slots, if subtasks are absent or are released late. Tasks with and without subtasks at time \( t \) are distinguished using the following definition of an active task.

**Definition 1:** A GIS task \( U \) is active at time \( t \) if it has a subtask \( U_j \) such that \( e(U_j) \leq t < d(U_j) \).

(A task that is active at \( t \) is not necessarily scheduled at \( t \).)

**Holes.** If fewer than \( M \) tasks are scheduled at time \( t \) in \( S \), then one or more processors would be idle at \( t \). If \( k \) processors are idle during \( t \), then we say that there are \( k \) holes in \( S \) at \( t \). The following lemma, proved in [15], relates an increase in the total lag of \( \tau \), \( LAG \), to the presence of holes.

**Lemma 2** [15] If \( LAG(\tau, t + 1) > LAG(\tau, t) \), then there are one or more holes in \( t \).

Intuitively, if there are no idle processors in slot \( t \), then the total allocation to \( \tau \) in \( S \) is at least the total allocation to \( \tau \) in the ideal system in slot \( t \). Therefore, \( LAG \) cannot increase.
**Task classification**[15]. Tasks in $\tau$ may be classified as follows with respect to a schedule $S$ and time $t$.

$A(t)$: Set of all tasks that are scheduled at $t$.

$B(t)$: Set of all tasks that are not scheduled at $t$, but are active at $t$.

$I(t)$: Set of all tasks that are neither active nor are scheduled at $t$.

$A(t), B(t),$ and $I(t)$ form a partition of $\tau$, i.e.,

$$\left( A(t) \cup B(t) \cup I(t) = \tau \right) \land \left( A(t) \cap B(t) = B(t) \cap I(t) = I(t) \cap A(t) = \emptyset \right).$$

This classification of tasks is illustrated in Fig. 3. Using (20) and (22) above, we have the following.

$$\text{LAG}(\tau, t + 1) = \sum_{T \in A(t)} \text{lag}(T, t + 1) + \sum_{T \in B(t)} \text{lag}(T, t + 1) + \sum_{T \in I(t)} \text{lag}(T, t + 1)$$

The next definition identifies the last-released subtask at $t$ of any task $U$.

**Definition 2**: Subtask $U_j$ is the critical subtask of $U$ at $t$ iff $e(U_j) \leq t < d(U_j)$ holds, and no other subtask $U_k$ of $U$, where $k > j$, satisfies $e(U_k) \leq t < d(U_k)$. For example, in Fig. 3, $T_{i+1}$ is the critical subtask of $T$ at both $t-1$ and $t$, and $U_{k+1}$ is that of $U$ at $t+1$.

**Displacements.** In our proof, we consider task systems obtained by removing subtasks. If $S$ is a schedule for a GIS task system $\tau$, then removing a subtask from $\tau$ results in another GIS system $\tau'$, and may cause other subtasks to shift earlier in $S$, resulting in a schedule $S'$ that is valid for $\tau'$. Such a shift is called a displacement and is denoted by a 4-tuple $(X^{(1)}, t_1, X^{(2)}, t_2)$, where $X^{(1)}$ and $X^{(2)}$ represent subtasks. This is equivalent to saying that subtask $X^{(2)}$ originally scheduled at $t_2$ in $S$ displaces subtask $X^{(1)}$ scheduled at $t_1$ in $S$. A displacement $(X^{(1)}, t_1, X^{(2)}, t_2)$ is valid iff $e(X^{(2)}) \leq t_1$. Because there can be a cascade of shifts, we may have a chain of displacements. This chain is represented by a sequence of 4-tuples. For an example of a displacement chain, refer to Fig. 4.

The next lemma concerns displacements and is proved in [15]. It states that a subtask removal can only cause left shifts.

---

2For brevity, we let the task system $\tau$ and schedule $S$ be implicit in these definitions.
Lemma 3 [15] Let $X^{(1)}$ be a subtask that is removed from $\tau$, and let the resulting chain of displacements in an EPDF schedule for $\tau$ be $C = \Delta_1, \Delta_2, \ldots, \Delta_k$, where $\Delta_i = (X^{(i)}, t_i, X^{(i+1)}, t_{i+1})$. Then $t_{i+1} > t_i$ for all $i \in [1, k]$.

3 Sufficient Schedulability Test for EPDF

In this section, we establish a sufficient schedulability test for EPDF by deriving a schedulable utilization bound for it, given by the following theorem.

Theorem 1 \[ \frac{(k(k-1)M+1)((k-1)W_{\text{max}}+k)-1}{k^2(k-1)(1+W_{\text{max}})} \], where $W_{\text{max}}$ is the maximum weight of any task in $\tau$ and $k = \left\lceil \frac{1}{W_{\text{max}}} \right\rceil + 1$, is a schedulable utilization bound of EPDF for scheduling a GIS task system $\tau$ on $M > 2$ processors.

As a shorthand, we define $U(M, W_{\text{max}})$ as follows.

**Definition 3:** $U(M, W_{\text{max}}) \stackrel{\text{def}}{=} \frac{(k(k-1)M+1)((k-1)W_{\text{max}}+k)-1}{k^2(k-1)(1+W_{\text{max}})}$, where $k = \left\lceil \frac{1}{W_{\text{max}}} \right\rceil + 1$.

For simplicity, we prove the theorem for $k = 2$, i.e., when the following holds.

\[ \frac{1}{2} < W_{\text{max}} \leq 1 \]  \hspace{1cm} (24)

Later, we show how to extend the proof for $k > 2$. Because $W_{\text{max}} \leq 1$, we have $k \geq 2$. When $k = 2$, $U(M, W_{\text{max}})$ reduces to \[ \frac{(2M+1)(2+W_{\text{max}})-1}{4(1+W_{\text{max}})} \], i.e., $U(M, W_{\text{max}}) = \frac{(2M+1)(2+W_{\text{max}})-1}{4(1+W_{\text{max}})}$, for all $\frac{1}{2} < W_{\text{max}} \leq 1$.

We use the proof technique developed by Srinivasan and Anderson in [16] to prove the above theorem. If Theorem 1 does not hold, then $t_d$ and $\tau$ defined as follows exist. (In these definitions, we assume that $\tau$ is scheduled on $M$ processors.)

**Definition 4:** $t_d$ is the earliest time that any task system (with each task weight at most $W_{\text{max}}$ and total utilization at most $U(M, W_{\text{max}})$) has a deadline miss under EPDF, i.e., some such task system misses a subtask deadline at $t_d$, and no such system misses a subtask deadline prior to $t_d$.

**Definition 5:** $\tau$ is a task system with the following properties.

(T1) $t_d$ is the earliest time that a subtask in $\tau$ misses its deadline under $S$, an EPDF schedule for $\tau$.

(T2) The weight of every task in $\tau$ is at most $W_{\text{max}}$ and the total utilization of $\tau$ is at most $U(M, W_{\text{max}})$.

(T3) No other task system satisfying (T1) and (T2) releases fewer subtasks in $[0, t_d)$ than $\tau$.
(T4) No other task system satisfying (T1), (T2), and (T3) has a larger rank than $\tau$ at $t_d$, where the rank of a system $\tau$ at $t$ is the sum of the eligibility times of all subtasks with deadlines at most $t$, i.e., $\text{rank}(\tau, t) = \sum_{T_i : T_i \in \tau \land d(T_i) \leq t} e(T_i)$.

By (T1) and (T3), exactly one subtask in $\tau$ misses its deadline: if several such subtasks exist, then all but one can be removed and the remaining subtask will still miss its deadline, contradicting (T3). The following shorthand notation will be used hereafter.

**Definition 6**: $\alpha$ denotes the total utilization of $\tau$, expressed as a fraction of $M$, i.e., $\sum_{T \in \tau} \text{wt}(T) = \alpha M$.

**Definition 7**: $\delta \overset{\text{def}}{=} \frac{W_{\text{max}}}{1 + W_{\text{max}}}$.

The lemma below follows from the definitions of $U$ and $\alpha$, (T2), and Lemma 19, proved in an appendix.

**Lemma 4** $0 \leq \alpha \leq \frac{U(M, W_{\text{max}})}{M} < 1$, for all $M \geq 2$.

The next lemma is immediate from the definition of $\delta$ and (24).

**Lemma 5** $\frac{1}{3} < \delta \leq \frac{1}{2}$.

We now prove some properties about $\tau$ and $S$. In proving some of these properties, we make use of the following three lemmas established in prior work by Srinivasan and Anderson.

**Lemma 6** [15] If $\text{LAG}(\tau, t + 1) > \text{LAG}(\tau, t)$, then $B(t) \neq \emptyset$.

The following is an intuitive explanation for why Lemma 6 holds. Recall from Sec. 2 that $B(t)$ is the set of all tasks that are active and not scheduled at $t$. By Def. 1 and (14), only tasks that are active at $t$ may have non-zero shares at $t$ in the ideal system. Therefore, if every task that is active at $t$ is scheduled at $t$, then the total allocation in $S$ cannot be less than the total allocation in the ideal system, and hence, by (21), $\text{LAG}$ cannot increase across slot $t$.

**Lemma 7** [14] Let $t < t_d$ be a slot with holes and let $T \in B(t)$. Then, the critical subtask at $t$ of $T$ is scheduled before $t$.

To see that the above lemma holds, let $T_i$ be the critical subtask of $T$ at $t$. By its definition, the IS-window of $T_i$ overlaps slot $t$, but $T$ is not scheduled at $t$. Also, there is at least a hole in $t$. Because EPDF does not idle a processor while there is a task with an outstanding execution request, it should be the case that $T_i$ is scheduled before $t$.

**Lemma 8** [15] Let $U_j$ be a subtask that is scheduled in slot $t'$, where $t' \leq t < t_d$, in $S$, where there is a hole in $t$. Then, $d(U_j) \leq t + 1$.

This lemma is true because it can be shown that if $d(U_j) > t + 1$ holds, then $U_j$ has no impact on the deadline miss at $t_d$. In other words, it can be shown that if the lemma does not hold, then the task system obtained from $\tau$ by removing $U_j$ also has a deadline miss at $t_d$, which is a contradiction to (T3).
Lemma 9 The following properties hold for $\tau$ and $S$.

(a) For all $T_i$, $d(T_i) \leq t_d$.

(b) Exactly one subtask of $\tau$ misses its deadline at $t_d$.

(c) $\text{LAG}(\tau, t_d) = 1$.

(d) $(\forall T_i :: d(T_i) < t_d \Rightarrow (\exists t :: e(T_i) \leq t < d(T_i) \land S(T_i, t) = 1))$.

(e) Let $U_k$ be the subtask that misses its deadline at $t_d$. Then, $U$ is not scheduled at $t_d − 1$.

(f) There are no holes in slot $t_d − 1$.

(g) There exists a time $v \leq t_d − 2$ such that the following both hold.
   
   (i) There are no holes in $[v, t_d − 2)$.
   
   (ii) $\text{LAG}(\tau, v) \geq (t_d − v)(1 − \alpha)M + 1$.

(h) There exists a time $u \in [0, t_d − 3]$ such that $\text{LAG}(\tau, u) < 1$ and $\text{LAG}(\tau, u + 1) \geq 1$.

Parts (a), (b), and (c) are proved in [15]. Part (d) follows directly from (T1). The rest are proved in an appendix.

Overview of the rest of the proof of Theorem 1. By Lemma 9(h), if $t_d$ and $\tau$ as defined by Defs. 4 and 5, respectively, exist, then there exists a time slot $u < t_d − 2$ across which $\text{LAG}$ increases to at least one. To prove Theorem 1, we show that for every such $u$, either (i) there exists a time $u'$, where $u + 1 < u' \leq t_d$, such that $\text{LAG}(\tau, u') < 1$, and thereby derive a contradiction to Lemma 9(c), or (ii) there does not exist a $v \leq t_d − 2$ such that there are no holes in $[v, t_d − 2)$ and $\text{LAG}(\tau, v) > (t_d − v)(1 − \alpha)M$, deriving a contradiction to Lemma 9(g). In what follows, we state and prove several other lemmas that are required to accomplish this.

The first lemma shows that $\text{LAG}$ does not increase across slot zero.

Lemma 10 $\text{LAG}(\tau, 1) \leq \text{LAG}(\tau, 0) = 0$.

Proof: Assume to the contrary that $\text{LAG}(\tau, 1) > \text{LAG}(\tau, 0)$. Then, by Lemma 6, $B(0) \neq \emptyset$ holds. Let $T$ be a task in $B(0)$ and let $T_i$ be its critical subtask at time zero. Then, by Lemma 7, $T_i$ is scheduled before time zero, which is impossible. Therefore, our assumption that $\text{LAG}(\tau, 1) > 0$ holds is incorrect. \qed

Lemma 2 showed that one or more holes in slot $t$ are necessary for $\text{LAG}$ to increase across $t$. The next lemma shows that there are no holes in slot $t − 1$ in this case.

Lemma 11 If $\text{LAG}(\tau, t + 1) > \text{LAG}(\tau, t)$, where $1 \leq t < t_d − 2$, then there are no holes in slot $t − 1$.
**Proof:** Contrary to the statement of the lemma, assume the following.

**(B)** There is a hole in slot \( t - 1 \).

By Lemma 8, this assumption implies that the deadline of every subtask \( T_i \) scheduled at \( t - 1 \) is at most \( t \). Because \( t < t_d \) holds, by Lemma 9(d), \( T_i \) does not miss its deadline. Therefore, we have the following.

\[
(\forall T_i :: S(T_i, t - 1) = 1 \Rightarrow d(T_i) = t)
\]  

(25)

Because \( LAG(\tau, t + 1) > LAG(\tau, t) \) holds (by the statement of the Lemma), by Lemma 6, \( B(t) \) is not empty. Let \( U \) be any task in \( B(t) \) and let \( U_j \) be its critical subtask at \( t \). Then, by Lemma 7, \( U_j \) is scheduled before \( t \) in \( S \), say at \( t' \), i.e.,

\[
S(U_j, t') = 1 \land t' < t.
\]

(26)

Also, by Def. 2,

\[
d(U_j) \geq t + 1.
\]

(27)

Let \( \tau' \) be the task system obtained by removing \( U_j \) from \( \tau \), and let \( S' \) be the schedule that results due to the left shifts caused in \( S \) by \( U_j \)'s removal. We show that the left shifts do not extend beyond slot \( t - 1 \), which would imply that a deadline is still missed at \( t_d \) in \( S' \). This in turn would imply that \( \tau' \), with one subtask fewer than \( \tau \), also has a deadline miss at \( t_d \), contradicting (T3).

Let \( \Delta_1, \Delta_2, \ldots, \Delta_n \) be the chain of displacements in \( S \) caused by removing \( U_j \), where \( \Delta_i = \langle X^{(i)}, t_i, X^{(i+1)}, t_{i+1} \rangle \), \( 1 \leq i < n \), and \( X^{(1)} = U_j \). By Lemma 3, \( t_i < t_{i+1} \) holds for all \( 1 \leq i \leq n \). By (26), \( t_1 = t' < t \) holds, as illustrated in Fig. 5. Because EPDF scheduled \( X^{(i)} \) at \( t_i \) in preference to \( X^{(k)} \) in \( S \), where \( i < k \leq n + 1 \), the priority of \( X^{(i)} \) is at least as high as that of \( X^{(k)} \). In other words, we have \( d(X^{(i)}) \leq d(X^{(k)}) \), for all \( 1 \leq i < k \leq n + 1 \). Because \( X^{(1)} = U_j \), by (27), this implies the following.

\[
(\forall k : 1 \leq k \leq n + 1 :: d(X^{(k)}) \geq t + 1)
\]

(28)

We next show that the chain of displacements does not extend beyond slot \( t - 1 \). Suppose that the displacements extend beyond slot \( t - 1 \). Let \( \Delta_h, 1 \leq h \leq n \) be the displacement with the smallest index such that \( t_h \leq t - 1 \) and \( t_{h+1} \geq t \) holds. Because \( \Delta_h \) is valid, \( c(X^{(h+1)}) \leq t_h \) holds. Now, if \( t_h < t - 1 \), then since there is a hole in slot \( t - 1 \), \( X^{(h+1)} \) should have...
been scheduled at $t - 1$ in $S$ and not at $t_{h+1} \geq t$. Therefore, $t_{h} = t - 1$, i.e., $X^{(h)}$ is scheduled at $t - 1$ in $S$. Hence, by (25), we have $d(X^{(h)}) = t$, which contradicts (28). This is illustrated in Fig. 5. Thus, the displacements do not extend beyond $t - 1$, which implies that a deadline is still missed at $t_d$, contradicting (T3). Therefore, our assumption in (B) is false. □

The next lemma bounds the lag of each task at time $t + 1$, where $t$ is a slot with one or more holes.

**Lemma 12** If $t < t_d$ is a slot with one or more holes, then the following hold.

(a) $(\forall T \in A(t)) \colon lag(T, t + 1) < wt(T)$

(b) $(\forall T \in B(t)) \colon lag(T, t + 1) \leq 0$

(c) $(\forall T \in I(t)) \colon lag(T, t + 1) = 0$

**Proof:** Parts (b) and (c) have been proved in [16]. We prove part (a) here. Let $T$ be a task in $A(t)$ and let $T_i$ be its subtask scheduled at $t$. Therefore, $T_i$ and all prior subtasks of $T$ are scheduled in $[0, t + 1)$, i.e., these subtasks receive their entire allocation of one quantum in $[0, t + 1)$ in $S$. Because there is a hole in $t$, by Lemma 8, we have $d(T_i) \leq t + 1$. Because $t < t_d$ holds, by Lemma 9(d), $T_i$ does not miss its deadline. Hence, we have $d(T_i) = t + 1$. By (18) and the final part of (14) this implies that $T_i$ and all prior subtasks of $T$ receive an allocation of one quantum each in $[0, t + 1)$ in the ideal system also. Therefore, any difference in allocation between the ideal system and $S$ is only due to subtasks that are released later than $T_i$. This is illustrated in Fig. 6.

Obviously, every subtask that is released later than $T_i$ receives an allocation of zero in $S$ in $[0, t + 1)$. Therefore, the lag of $T$ at $t + 1$ is equal to the shares that these later subtasks receive in the ideal system in the same interval. To determine this value, let $T_j$ be the successor of $T_i$. Recall from Sec. 2 that the PF-window of $T_i$ may overlap with that of $T_j$ only if $j = i + 1$ and that the overlap may be over at most one slot. Therefore, among the later subtasks, only $T_{i+1}$ may receive a non-zero allocation in $[0, t)$. In particular, the allocation may be non-zero only in slot $t$. Therefore, if $T_i$ and $T_{i+1}$ are non-overlapping (or $T_{i+1}$ is absent), then $lag(T, t)$ is equal to zero. Otherwise, it is given by the share that $T_{i+1}$ receives in slot $t$. In that case, by (16) and (17), $f(T_i, t) + f(T_{i+1}, t) = wt(T)$. Because, by (14), $f(T_i, t)$ is positive, we have $f(T_{i+1}, t) < wt(T)$, and hence, $lag(T, t) < wt(T)$. This is illustrated in Fig. 6. □
The next lemma gives an upper bound on $LAG$ at $t + 1$ in terms of $LAG$ at $t$ and $t - 1$, when $LAG$ increases across slot $t$.

**Lemma 13** Let $t$, where $1 \leq t < t_d - 2$, be a slot such that there is at least a hole in slot $t$ and there is no hole in slot $t - 1$. Then $LAG(\tau, t + 1) \leq LAG(\tau, t) \cdot \delta + \alpha M \cdot \delta$ and $LAG(\tau, t + 1) \leq LAG(\tau, t - 1) \cdot \delta + (2\alpha M - M) \cdot \delta$.

**Proof:** By the statement of the lemma, there is at least one hole in slot $t$. Therefore, by Lemma 12, only tasks that are scheduled in slot $t$, i.e., tasks in set $A(t)$, may have a positive lag at $t + 1$. Let $x$ denote the number of tasks scheduled at $t$, i.e., $x = \sum_{T \in \tau} S(T, t) = |A(t)|$. Then, by (23), we have

$$LAG(\tau, t + 1) \leq \sum_{T \in A(t)} lag(T, t + 1)$$

$$< \sum_{T \in A(t)} wt(T)$$

$$\leq \sum_{T \in A(t)} W_{\max}$$

$$= |A(t)| \cdot W_{\max}$$

$$= x \cdot W_{\max}.$$

(29)

Using (21), $LAG(\tau, t + 1)$ can be expressed as follows.

$$LAG(\tau, t + 1) = LAG(\tau, t) + \sum_{T \in \tau} (share(T, t) - S(T, t))$$

$$= LAG(\tau, t) + \sum_{T \in \tau} share(T, t) - x$$

$$\leq LAG(\tau, t) + \sum_{T \in \tau} wt(T) - x$$

$$= LAG(\tau, t) + \alpha M - x$$

(30)

By (29) and (30), we have

$$LAG(\tau, t + 1) \leq \min(x \cdot W_{\max}, LAG(\tau, t) + \alpha M - x).$$

(31)

Because $x \cdot W_{\max}$ increases with increasing $x$, whereas $LAG(\tau, t) + \alpha M - x$ decreases, $LAG(\tau, t + 1)$ is maximized when $x \cdot W_{\max} = LAG(\tau, t) + \alpha M - x$, i.e., when $x = \frac{LAG(\tau, t)}{1 + W_{\max}} + \frac{\alpha M}{1 + W_{\max}}$. Therefore, using either (29) or (30), we have

$$LAG(\tau, t + 1) \leq LAG(\tau, t) \cdot \left(\frac{W_{\max}}{1 + W_{\max}}\right) + \alpha M \cdot \left(\frac{W_{\max}}{1 + W_{\max}}\right)$$

$$= LAG(\tau, t) \cdot \delta + \alpha M \cdot \delta$$

(32)

By the statement of the lemma again, there is no hole in slot $t - 1$. (Also, $t \geq 1$, and hence, $t - 1$ exists.) Therefore, using (21), $LAG(\tau, t)$ can be expressed as follows.

$$LAG(\tau, t) = LAG(\tau, t - 1) + \sum_{T \in \tau} (share(T, t - 1) - S(T, t - 1))$$
\[ LAG(\tau, t - 1) + \sum_{T \in \tau} share(T, t - 1) - M = \sum_{T \in \tau} S(T, t - 1) = M \] (there are no holes in \( t - 1 \))

by (17) and Def. 6

Substituting (33) in (32), we have

\[ LAG(\tau, t + 1) \leq LAG(\tau, t - 1) \cdot \delta + (2\alpha M - M) \cdot \delta. \]

The next lemma shows how to bound \( LAG \) at the end of an interval that does not contain two consecutive slots without holes, after \( LAG \) increases to one at the beginning of the interval.

**Lemma 14** Let \( 1 \leq t < t_d - 2 \) be a slot across which \( LAG \) increases to one, i.e.,

\[ 1 \leq t < t_d - 2 \land LAG(\tau, t) < 1 \land LAG(\tau, t + 1) \geq 1. \] (34)

Let \( u \), where \( t < u < t_d \), be such that there is at least one hole in \( u - 1 \) and there are no two consecutive slots without holes in the interval \([t + 1, u)\). Then, \( LAG(\tau, u) < (2 - 2\alpha)M + 1. \)

**Proof:** Because (34) holds, by Lemmas 2 and 11, we have (C1) and (C2), respectively.

(C1) There is at least one hole in slot \( t \).

(C2) There is no hole in slot \( t - 1 \).

By (C1) and the definition of \( u \), we have the following.

\[ (\forall t' : t \leq t' \leq u - 1 :: \text{there is a hole in } t' \text{ or } t' + 1) \] (35)

Let \( t_1, t_2, \ldots, t_n \), where \( t < t_1 < t_2 < \ldots < t_n < u - 1 \) be the slots without holes in \([t, u)\). Then, by (C1) and (35), there is at least one hole in each of \( t_i - 1 \) and \( t_i + 1 \) for all \( 1 \leq i \leq n \).

We divide the interval \([t - 1, u)\) into \( n + 1 \) non-overlapping subintervals using the slots without holes \( t - 1, t_1, \ldots, t_n \), as shown in Fig. 7. The subintervals denoted \( I_0, I_1, \ldots, I_n \) are defined as follows.

\[
I_0 \overset{\text{def}}{=} \begin{cases} [t - 1, t_1), & \text{if } t_1 \text{ exists} \\ [t - 1, u), & \text{otherwise} \end{cases}
\] (36)

\[
I_n \overset{\text{def}}{=} [t_n, u)
\] (37)

\[
I_k \overset{\text{def}}{=} [t_k, t_{k+1}), \text{ for all } 1 \leq k < n
\] (38)

Because \( t > 1 \) and \( u < t_d \) hold (by the statement of the Lemma), \( I_0 \) exists, and hence, we have

\[ n \geq 0. \] (39)
Figure 7. Lemma 14. \( \text{LAG}(\tau, t) < 1 \) and \( \text{LAG}(\tau, t + 1) \geq 1 \). No two consecutive slots in \([t-1, u)\) are without holes. The objective is to determine a bound on \( \text{LAG}(\tau, u) \).

Before proceeding further, the following notation is in order. We denote the start and end times of \( I_k \), where \( 0 \leq k \leq n \), by \( t_{s}^{k} \) and \( t_{f}^{k} \), respectively, \( i.e., I_k \) is denoted as follows.

\[
I_k \overset{\text{def}}{=} [t_{s}^{k}, t_{f}^{k}), \quad \text{for all } k = 0, 1, \ldots, n. \tag{40}
\]

LAG at \( t_{s}^{k} + 2 \) is denoted \( L_{k} \), \( i.e., \)

\[
L_{k} \overset{\text{def}}{=} \text{LAG}(\tau, t_{s}^{k} + 2), \quad \text{for all } k = 0, 1, \ldots, n. \tag{41}
\]

Note that the end of each subinterval is defined so that the following property holds.

(\textbf{C3}) For all \( k, 0 \leq k \leq n \), there is no hole in slot \( t_{s}^{k} \) and there is at least one hole in every slot \( \hat{t} \), where \( t_{s}^{k} + 1 \leq \hat{t} < t_{f}^{k} \).

Our goal now is to derive bounds for \( \text{LAG} \) at \( t_{f}^{k} \), for all \( 0 \leq k \leq n \). Towards this end, we first establish the following claim.

\textbf{Claim 1} \((\forall k, t' : 0 \leq k \leq n, t_{s}^{k} + 2 \leq t' \leq t_{f}^{k} : \text{LAG}(\tau, t') \leq L_{k})\).

The proof is by induction on \( t' \).

\textbf{Base Case:} \( t' = t_{s}^{k} + 2 \). The claim holds by (41).

\textbf{Induction Step:} Assuming that the claim holds at all times in the interval \([t_{s}^{k} + 2, t']\), where \( t_{s}^{k} + 2 \leq t' < t_{f}^{k} \), we show that it holds at \( t' + 1 \). By this induction hypothesis, we have

\[
\text{LAG}(\tau, t') \leq L_{k}. \tag{42}
\]

Because \( t' < t_{f}^{k} \) and \( t' \geq t_{s}^{k} + 2 \) hold (by the induction hypothesis), by (C3), there is at least one hole in both \( t' \) and \( t' - 1 \). Therefore, by the contrapositive of Lemma 11, \( \text{LAG}(\tau, t' + 1) \leq \text{LAG}(\tau, t') \), which by (42), is at most \( L_{k} \).

\( \square \)
Having shown that $LAG(\tau, t_\xi^f)$ is at most $L_k$, we now bound $L_k$. We start by determining a bound for $L_0$. From (36) and (40), we have $t_\xi^0 = t - 1$. Therefore, $t_\xi^0 + 2 = t + 1$. Because (C1) and (C2) hold, by Lemma 13,

$$L_0 = LAG(\tau, t + 1) \leq \delta \cdot LAG(\tau, t) + \delta \cdot \alpha M < \delta + \delta \cdot \alpha M,$$

by (34). (43)

We next determine an upper bound for $L_k$, where $1 \leq k \leq n$. Notice that by our definition of $I_k$ in (38), we have $t_k^s = t_k^s - 1$. Thus, $LAG(\tau, t_k^s + 1) = LAG(\tau, t_k^s - 1)$, and hence, by Claim 1, we have

$$LAG(\tau, t_k^s) \leq L_{k-1}. \quad (44)$$

By (C3), there is a hole in slot $t_k^s + 1$ and no hole in slot $t_k^s$. Therefore, by Lemma 13, $LAG(\tau, t_k^s + 2) \leq \delta \cdot LAG(\tau, t_k^s) + \delta \cdot (2\alpha M - M)$, which by (41) and (44) implies that

$$L_k = LAG(\tau, t_k^s + 2) \leq \delta \cdot L_{k-1} + \delta \cdot (2\alpha M - M). \quad (45)$$

By (37) and (40), we have $u = t_j^n$. Therefore, by Claim 1 and (39), we have

$$LAG(\tau, u) = LAG(\tau, t_j^n) \leq L_n, \quad (46)$$

and hence, an upper bound on $LAG(\tau, u)$ can be determined by solving the recurrence given by (43) and (45), which is restated below for convenience.

$$L_0 < \delta + \delta \cdot \alpha M$$

$$L_k \leq \delta \cdot L_{k-1} + \delta \cdot (2\alpha M - M)$$

By Lemma 20 (proved in an appendix), a solution to the above recurrence is given by

$$L_k < \delta^{k+1}(1 + \alpha M) + (1 - \delta) \left( \frac{\delta}{1 - \delta} \right) (2\alpha M - M). \quad (47)$$

Therefore, $LAG(\tau, u) \leq L_n < \delta^{n+1}(1 + \alpha M) + (1 - \delta^n) \left( \frac{\delta}{1 - \delta} \right) (2\alpha M - M)$.

If $L_n$ is at least $(2 - 2\alpha)M + 1$, then $\delta^{n+1}(1 + \alpha M) + (1 - \delta^n) \left( \frac{\delta}{1 - \delta} \right) (2\alpha M - M) > (2 - 2\alpha)M + 1$, which on rearranging terms implies that

$$\alpha > \frac{M(2 - \delta - \delta^{n+1}) + \delta^{n+2} - \delta^{n+1} + 1 - \delta}{M(2 - \delta^{n+1} - \delta^{n+2})} \geq \frac{M(2 - \delta) + \frac{1}{2}}{2M},$$

by Lemma 21 (proved in an appendix), and $0 \leq \delta \leq 1/2$ (by Lemma 5).
Lemma 15 Let \( 2t + 1 \geq 2 + W_{\text{max}} \). By the assumption for this case, there are no holes in consecutive slots in the interval \( u \). Because (48) is in contradiction to Lemma 4, we conclude that \( L_n < (2 - 2\alpha)M + 1 \). Hence, by (46), \( \text{LAG}(\tau, u) \leq L_n < (2 - 2\alpha)M + 1 \).

Lemma 15 Let \( t < t_d - 2 \) be a slot such that \( \text{LAG}(\tau, t) < 1 \) \& \( \text{LAG}(\tau, t + 1) \geq 1 \) and let \( u \) be the earliest time after \( t \) such that \( u = t_d - 2 \) or there no no holes in each of \( u \) and \( u + 1 \). (Note that this implies that no two consecutive slots in \([t + 1, u]\) are without holes.) Then, at least one of the following holds.

\[
\begin{align*}
  u &\leq t_d - 2, \text{ there are no holes in both } u \text{ and } u + 1, \text{ and } \text{LAG}(\tau, u + 2) < 1. \\
  u &\geq t_d - 2, \text{ there is at least a hole in } t_d - 3, \text{ and } \text{LAG}(\tau, t_d - 2) < 2(1 - \alpha)M. \\
  u &\geq t_d - 2, \text{ there is no hole in } t_d - 3, \text{ at least a hole in } t_d - 4, \text{ LAG}(\tau, t_d - 3) < 3(1 - \alpha)M,
  \text{ and } \text{LAG}(\tau, t_d - 2) < 2(1 - \alpha)M.
\end{align*}
\]

Proof: Because \( \text{LAG}(\tau, t + 1) > \text{LAG}(\tau, t) \) holds (by the statement of the lemma), by Lemma 2, we have the following.

(D1) There is at least a hole in \( t \).

We consider two cases depending on \( u \).

Case 1: \( u \leq t_d - 2 \) and there is no hole in \( u \).

We first prove that there is at least one hole in slot \( u - 1 \). If \( u = t + 1 \) holds, then by (D1), there is a hole in \( t = u - 1 \); if \( u \neq t + 1 \), then the absence of holes in \( u - 1 \) would contradict the fact that \( u \) is the earliest time after \( t \) such that either there is no hole in both \( u \) and \( u + 1 \) or \( u = t_d - 2 \). Thus, there is at least one hole in \( u - 1 \), and by the definition of \( u \), no two consecutive slots in the interval \([t + 1, u]\) are without holes. Therefore, by Lemma 14, we have \( \text{LAG}(\tau, u) < (2 - 2\alpha)M + 1 \).

To show that \( \text{LAG}(\tau, u + 2) < 1 \) holds, we next show that there are no holes in \( u + 1 \). On the other hand, if \( u = t_d - 2 \), then there are no holes in \( u + 1 = t_d - 1 \) by Lemma 9(f). By the assumption for this case, there are no holes in \( u \) either. Therefore, by (21), we have

\[
\begin{align*}
  \text{LAG}(\tau, u + 2) &\leq \text{LAG}(\tau, u) + \sum_{v=u+1}^{u+2} \sum_{T \in \tau} (\text{share}(T, v) - S(T, v)) \\
  &\leq \text{LAG}(\tau, u) + \sum_{v=u+1}^{u+2} \sum_{T \in \tau} \text{share}(T, v) - 2M \\
  &\leq (2 - 2\alpha)M + 1 + \sum_{v=u+1}^{u+2} \sum_{T \in \tau} \text{wt}(T) - 2M, \text{ by (17)} \\
  &\leq (2 - 2\alpha)M + 1 + 2\alpha M - 2M, \text{ by Def. 6}
\end{align*}
\]
Thus, condition (49) holds for this case.

**Case 2:** $u = t_d - 2$ and there is a hole in slot $t_d - 2$.

Because $u = t_d - 2$ holds for this case, by the definition of $u$, the following holds.

(D2) No two consecutive slots in $[t + 1, t_d - 2]$ are without holes.

Let $u' < t_d - 2$ denote the last slot with no hole in $[t + 1, t_d - 2]$. We consider the following two subcases.

**Subcase 2a:** $t < u' < t_d - 3$ or there is at least a hole in every slot in $[t + 1, t_d - 2]$. If $t < u' < t_d - 3$ holds, then by the definition of $u'$, there is at least a hole in $t_d - 3$. On the other hand, if there is no slot without a hole in $[t + 1, t_d - 2]$, then, because $t < t_d - 2$ holds (by the statement of the lemma), by (D1), there is a hole in $t_d - 3$. Therefore, by (D2) and because $\text{LAG}(\tau, t + 1) > \text{LAG}(\tau, t)$ holds (by the statement of the Lemma), Lemma 14 applies with $u = t_d - 2$. Hence, by Lemma 14, we have $\text{LAG}(\tau, t_d - 2) < (2 - 2\alpha)M + 1$. Therefore, for this case, (50) is satisfied.

**Subcase 2b:** $t < u' = t_d - 3$. Because there is no hole in slot $t_d - 3$ (by the assumption of this subcase), (D2) implies that there is at least a hole in slot $t_d - 4$.

(Because $t_d - 3 > t$ holds (by the assumption of this subcase again), $t_d - 4$ exists.) Therefore, because $\text{LAG}(\tau, t + 1) > \text{LAG}(\tau, t)$ holds, Lemma 14 applies with $u = t_d - 3$. Hence,

\[
\text{LAG}(\tau, t_d - 3) < (2 - 2\alpha)M + 1, \text{ by Lemma 14} \tag{52}
\]

\[
< (3 - 3\alpha)M + 1, \text{ by Lemma 4.} \tag{53}
\]

Further, by (21), we have

\[
\text{LAG}(\tau, t_d - 2) = \text{LAG}(\tau, t_d - 3) + \sum_{T \in \tau} (\text{share}(T, t_d - 3) - S(T, t_d - 3))
\]

\[
< (2 - 2\alpha)M + \sum_{T \in \tau} (\text{share}(T, t_d - 3) - S(T, t_d - 3)), \text{ by (52)}
\]

\[
= (2 - 2\alpha)M + \sum_{T \in \tau} \text{share}(T, t_d - 3) - M
\]

\[
, \text{there are no holes in } t_d - 3 \text{ (by the assumption of this subcase)}
\]

\[
\leq (2 - 2\alpha)M + \sum_{T \in \tau} w(T) - M, \text{ by (17)}
\]

\[
= (2 - 2\alpha)M + \alpha M - M, \text{ by Def. 6}
\]

\[
< (2 - 2\alpha)M, \text{ by Lemma 4.} \tag{54}
\]

By (D2), (53), and (54), condition (51) holds. $$\square$$
By part (h) of Lemma 9, there exists a $u$, where $0 \leq u < t_d - 2$, such that $LAG(\tau, u) < 1$ and $LAG(\tau, u + 1) \geq 1$. Let $t$ be the largest such $u$. Then, by Lemma 15, one of the following holds.

(a) There exists a $t'$, where $t' \leq t_d$, such that $LAG(\tau, t') < 1$.

(b) There does not exist a $v \leq t_d - 2$ such that there are no holes in $[v, t_d - 2)$ and $LAG(\tau, v) \geq (t_d - v)(1 - \alpha)M + 1$.

(This is implied by both (50) and (51).)

If (a) holds, and $t' < t_d$ holds, then this contradicts the maximality of $t$. On the other hand, if $t' = t_d$ holds, then it contradicts part (c) of Lemma 9. If (b) holds, then part (g) of the same lemma is contradicted. Therefore, our assumption that $\tau$ misses its deadline at $t_d$ is incorrect, which in turn proves Theorem 1, for $k = 2$.

As a corollary to Theorem 1, we have the following utilization-based schedulability test for EPDF.

**Corollary 1** A GIS task set $\tau$ is schedulable on $M > 2$ processors under EPDF if the total utilization of $\tau$ is at most $U(M, W_{max})$, where $W_{max}$ is the maximum weight of any task in $\tau$ and $U(M, W_{max})$ is given by Def. 3.

**Generalizing the proof.** The proof of Theorem 1 given above for $k = 2$ can be generalized to $k > 2$ as follows.

If $W_{max} \leq 1/2$, then it can be shown that for $LAG(\tau, t + 1) > LAG(\tau, t)$ to hold, there should be no holes in slots $t - 1$ and $t - 2$, which is a generalization of Lemma 11. In general, if $W_{max} \leq \frac{1}{e - \tau}$, then it can be shown that $k - 1$ slots preceding $t$ are without holes. Similarly, parts (f) and (g) of Lemma 9 can be generalized as follows. There are no holes in the last $k - 1$ slots (slots $[t_d - k + 1, t_d]$), and there exists a $v \leq t_d - k$ such that there are no holes in every slot in $[v, t_d - k)$ and $LAG(\tau, v) \geq (t_d - v)(1 - \alpha)M + 1$. A formal proof is omitted due to space constraints. Fig. 8 shows the plot of the schedulable utilization of EPDF (computed using the bound in Theorem 1 with a sufficiently large $M$, and expressed as a percentage of the total processing capacity) with respect to $W_{max}$. For comparison, plots of schedulable utilization for the partitioned approach [13] and the global approach that assigns a fixed priority to each job [6] (computed using their best known bounds expressed in terms of $W_{max}$), are also shown in the same figure.

Is the schedulable utilization bound given by Theorem 1 optimal? As yet, we do not know the answer to this question. However, as the following example shows, the general bound cannot be improved to exceed $0.86M$.

**Counterexample.** Consider a task set comprised of $2n + 1$ tasks of weight $\frac{1}{2}$, $n$ tasks of weight $\frac{3}{4}$, and $n$ tasks of weight $\frac{5}{6}$ scheduled on $3n$ processors. There is an EPDF schedule for this task set in which a deadline miss occurs at time...
12. (The schedule is not shown here due to space constraints.) The total utilization of this task set is \( \frac{31n}{12} + \frac{1}{2} \), which approaches 86.1% of 3n, the total processing capacity, as n approaches infinity. Given that devising counterexamples for Pfair scheduling algorithms is somewhat hard, we believe that it may not be possible to significantly improve the bound of Theorem 1, which is asymptotically 75% of the total processing capacity.

**Utilization restriction for a tardiness of q quanta.** Having determined a sufficient utilization restriction for schedulability under EPDF, we were interested in determining a sufficient utilization restriction for a tardiness of q quanta. Extending the technique used above, we found that if the total utilization of \( \tau \) is at most \( \frac{(5q+6)M}{5q+8} \), then no subtask of \( \tau \) misses its deadline by more than q quanta. (Again, a proof is omitted due to space constraints.) For a tardiness of at most one, this imposes a sufficient utilization restriction of 84.6%. We feel that this is somewhat restrictive and that it can be improved significantly by identifying and exploiting the right properties of a system with a tardiness of q. We have deferred this for future work.

4 Conclusion

We have determined a schedulable utilization bound for the earliest-pseudo-deadline-first (EPDF) Pfair scheduling algorithm, and thereby, presented a sufficient schedulability test for EPDF. In general, this test allows any task set with total utilization not exceeding \( \frac{3M+1}{4} \) to be scheduled on M processors. Our schedulability test is expressed in terms of the maximum weight of any task, and hence, may be used to schedule task sets with total utilization greater than \( \frac{3M+1}{4} \). We have also presented a counterexample that suggests that a significant improvement to the test may not be likely. Finally, we have extended the test to allow a tardiness of q quanta.

Appendix: Proofs Omitted in the Main Text

Lemma 16 Let $T$ be a unit-weight task. Then, $d(T_i) = r(T_i) + 1$ and $|w(T_i)| = 1$ hold for every subtask $T_i$ of $T$.

Proof: Follows directly from (10) and (9).

In some of the proofs that follow, we identify tasks that have a share of zero at time $t$ in the ideal system using the following definition.

Definition 8: A GIS task $U$ is a Z-task at time $t$ iff there exists no subtask $U_j$ such that $r(U_j) \leq t < d(U_j)$.

Note that (14) and (16) imply that $U$ is a Z-task at $t$ iff $\text{share}(U, t) = 0$.

Lemma 17 Let $T_i$ be a subtask of a unit-weight task $T$ scheduled at some time $t < t_d$. If $r(T_i) > t$, then there exists at least one slot $t'$ in $[0, t + 1)$ such that $T$ is a Z-task at $t'$.

Proof: Because this lemma is quite intuitive, we give an informal proof with the help of Fig. 9(a).

Assume to the contrary that $T$ is not a Z-task in any slot in $[0, t + 1)$. Then, by Def. 8, for every slot $u$ in $[0, t + 1)$, there exists some subtask whose PF-window overlaps $u$. By Lemma 16, the length of the PF-window of every subtask of $T$ is exactly one. Therefore, for every slot $u$ in $[0, t + 1)$, there exists a subtask $T_h$ that has to be scheduled in $u$ for $T_h$ to not miss its deadline. By (5) (and because $\theta(T_i)$ is non-negative) only subtask $T_1$ could have a release time of zero, and inductively, only subtask $T_{h+1}$ could have a release time of $t_h$, for all $0 \leq h \leq t$. This in turn implies that only subtask $T_{h+1}$ of $T$ could be scheduled at $t_h$. In particular, only subtask $T_{t+1}$ could be scheduled at time $t$, which contradicts the statement of the lemma. Therefore, our assumption that $T$ is not a Z-task in any slot in $[0, t + 1)$ is false.
Figure 9. (a) Lemma 17. If \( T \) is not a Z-task in \([0, t+1)\), then only subtask \( T_{t+1} \) can be scheduled at \( t \). (b) Lemma 18. \( T \) is not a Z-task in \([z+1, t+1)\) and no subtask of \( T \) is scheduled at \( t \). \( T_j, \ldots, T_f \) are the critical subtasks of \( T \) at \( z+1, \ldots, t \), respectively. Intervals demarcated with solid lines indicate PF-windows of subtasks (as in the other figures). Intervals marked with dotted lines indicate IS-windows. Arrows over the left end points of the IS-windows indicate that these end points could extend in the direction of the arrows. The slot in which a subtask is scheduled is indicated by an “X”. \( T_j \) is the critical subtask of \( T \) at \( t \), which is scheduled at \( t'' \). By Lemma 8, there are no holes in \([z, t)\).

Lemma 18 Let \( T \) be a unit-weight task and suppose \( T \) is not scheduled at some time \( t < t_d \), where there is at least one hole in \( t \). Then, there exists a time \( t' \leq t \), such that there are no holes in \([t', t)\) and there exists at least one slot \( i \) in \([t', t+1)\), such that \( T \) is a Z-task in \( i \).

Proof: Because \( T \) is not scheduled at \( t \), by (22), either \( T \in B(t) \) or \( T \in I(t) \). If \( T \in I(t) \), then \( T \) is a Z-task at \( t \). Therefore, the lemma is trivially satisfied with \( t' = t \). So assume \( T \in B(t) \) for the rest of the proof. Let \( T_j \) be the critical subtask at \( t \) of \( T \). Then, by Def. 2, we have

\[
d(T_j) \geq t + 1.
\]

Also, because there is a hole in \( t \), by Lemma 7, \( T_j \) is scheduled before \( t \), say \( t'' \), i.e.,

\[
t'' < t \land S(T_j, t'') = 1.
\]

Because there is a hole in \( t \), by Lemma 8, \( d(T_j) \leq t + 1 \) holds, which by (55) implies that \( d(T_j) = t + 1 \) holds. Because \( wt(T) = 1 \), by Lemma 16, we have \( r(T_j) = t \). Thus,

\[
r(T_j) = t \land d(T_j) = t + 1.
\]

Let \( z \) be the latest time before \( t \) such that \( T \) is a Z-task at \( z \). Because (56) and (57) hold, by Lemma 17, such a \( z \) exists. Therefore, we have

\[
0 \leq z < t \land (\exists T_k : r(T_k) \leq z \land d(T_k) > z) \land (\forall z' : z < z' \leq t : (\exists T_k : r(T_k) \leq z' \land d(T_k) > z')).
\]

Because \( wt(T) = 1 \) holds, by Lemma 16, (58) implies the following.

\[
0 \leq z < t \land (\exists T_k : r(T_k) = z \land d(T_k) = z + 1) \land (\forall z' : z < z' \leq t : (\exists T_k : r(T_k) = z' \land d(T_k) = z' + 1)).
\]
This is also illustrated in Fig. 9(b). We next show that the following holds.

\[(\forall z': z < z' \leq t :: (r(T_k) = z' \land d(T_k) = z' + 1) \Rightarrow (\exists u': u' \leq t'' - (t - z') < z' :: (S(T_k, u') = 1 \land \text{there are no holes in } [u', z']))\]  

(60)

The proof is by induction on \(z'\).

**Base Case:** \(z' = t\). By (57), we have \(r(T_j) = t\) and \(d(T_j) = t + 1\), and by (56), we have \(S(T_j, t'') = 1\). We also have \(t'' = t'' - (t - t')\) and \(t'' < t\). Therefore, to show that (60) holds, we only have to show that there are no holes in any slot in \([t'', t)\). Assume to the contrary that there is a hole in slot \(t_h\) in \([t'', t)\). Then, by Lemma 8, \(d(U_j) \leq t_h + 1 < t + 1\), which is in contradiction to (57). Therefore, there are no holes in any slot in \([t'', t)\).

**Induction Hypothesis:** Assume that for all \(z''\), where \(z'' \leq z' \leq t\) and \(t \geq z'' > z + 1\), \((r(T_k) = z' \land d(T_k) = z' + 1) \Rightarrow (\exists u': u' \leq t'' - (t - z') < z' :: (S(T_k, u') = 1 \land \text{there are no holes in } [u', z'])\) holds.

**Induction Step:** We now show that the following holds.

\[(r(T_k) = z'' - 1 \land d(T_k) = z'') \Rightarrow (\exists u': u' \leq t'' - (t - z'' - 1) < z'' :: (S(T_k, u') = 1 \land \text{there are no holes in } [u', z'' - 1]))\]  

(61)

By (59), there exists a subtask \(T_k\) such that \(r(T_k) = z'' - 1\) and \(d(T_k) = z''\). By the induction hypothesis, there exists a subtask \(T_i\) with \(r(T_i) = z''\) and \(d(T_i) = z'' + 1\), such that \(T_i\) is scheduled at or before \(t'' - (t - z'')\). Now, because \(r(T_k) < r(T_i)\) holds, by (7), \(T_k\) is scheduled before \(T_i\), i.e., \(T_k\) is scheduled at or before \(t'' - (t - z'') - 1 = t'' - (t - (z'' - 1))\). Because \(t'' - (t - (z'' - 1)) = z'' - 1 - (t - t'')\), by (56), we have \(t'' - (t - (z'' - 1)) < z'' - 1\). Thus, we have shown that if the left-hand-side of the implication in (61) holds, then the first subexpression on the right-hand-side is satisfied. To see that there are no holes in \([t'' - (t - (z'' - 1)), z'' - 1]\), assume to the contrary that there is a hole in slot \(t_h\) in this interval. Then, by Lemma 8, \(d(T_k) \leq t_h + 1 \leq z'' - 1\), which is in contradiction to \(d(T_k) = z''\). Therefore, there are no holes in any slot in \([t'' - (t - (z'' - 1)), z'' - 1]\). Thus, (60) holds for \(z'' - 1\).

(59) and (60) imply that \((\forall z': z < z' \leq t :: \text{there are no holes in } z' - 1)\). Therefore, it immediately follows that there are no holes in \([z, t)\). Also, we defined \(z\) such that \(T\) is a \(Z\)-task at \(z\). Therefore, the lemma follows.

\[\square\]

**Proof of parts (e), (f), (g), and (h) of Lemma 9.**

**Lemma 9** The following properties hold for \(\tau\) and \(S\).

(a) For all \(T_i\), \(d(T_i) \leq t_d\).
(b) Exactly one subtask of $\tau$ misses its deadline at $t_d$.

(c) $\text{LAG} (\tau, t_d) = 1$.

(d) $(\forall T_i :: d(T_i) < t_d \Rightarrow (\exists t :: e(T_i) \leq t < d(T_i) \land S(T_i, t) = 1))$

(e) Let $U_k$ be the subtask that misses its deadline at $t_d$. Then, $U$ is not scheduled at $t_d - 1$.

(f) There are no holes in slot $t_d - 1$.

(g) There exists a time $v \leq t_d - 2$ such that the following both hold.

(i) There are no holes in every slot in $[v, t_d - 2)$.

(ii) $\text{LAG} (\tau, v) \geq (t_d - v) (1 - \alpha) M + 1$.

(h) There exists a time $u \in [0, t_d - 3]$ such that $\text{LAG} (\tau, u) < 1$ and $\text{LAG} (\tau, u + 1) \geq 1$.

As mentioned in the main text, parts (a), (b), and (c) are proved in [15]. Part (d) follows directly from (T1). The rest are proved here.

Proof of (e): Let $U_k$ denote the subtask that misses its deadline at $t_d$. Then, for every $U_j$, where $j < k$, $d(U_j) < d(U_k) = t_d$, and hence, by part (d), $U_j$ is scheduled before $t_d - 1$. Obviously, no $U_l$, where $l > k$, is scheduled before $U_k$ is scheduled. Therefore, no subtask of $U$ is scheduled at $t_d - 1$. 

Proof of (f): Let $U_k$ denote the subtask that misses its deadline at $t_d$. Then, by part (e), no subtask of $U$ is scheduled at $t_d - 1$. Thus, if there is a hole in $t_d - 1$, then EPDF would schedule $U_k$ there, which contradicts the fact that $U_k$ misses its deadline.

Proof of (g): Define $\tau_1$ and $N_1$ as follows.

$$\tau_1 \overset{\text{def}}{=} \{ T : T \in \tau \land wt(T) = 1 \}$$

$$|\tau_1| \overset{\text{def}}{=} N_1$$

Then, we have

$$N_1 \leq M,$$

and

$$\sum_{T \in \tau - \tau_1} wt(T) = \alpha M - N_1 \quad \text{by Def. 6.}$$
Figure 10. Illustration for the lower bound on the number of tasks in $\tau - \tau_1$ scheduled at $t_d - 2$. As illustrated, every subtask of a non-unit-weight task scheduled at $t_d - 1$ is released at or before $t_d - 2$, and there are at least $M - N_1$ of them. The fact that these subtasks are not scheduled at $t_d - 2$ implies that there are at least $M - N_1$ other subtasks scheduled at $t_d - 2$.

By part (f), there are no holes in slot $t_d - 1$. Therefore, by (64), at least $M - N_1$ tasks with weight less than one (i.e., tasks in $\tau - \tau_1$) are scheduled at $t_d - 1$, i.e.,

$$\sum_{T \in \tau - \tau_1} S(T, t_d - 1) \geq M - N_1.$$  \hspace{1cm} (66)

Let

$$T = \{T_i : T \in \tau - \tau_1 \land S(T_i, t_d - 1) = 1\}.$$  \hspace{1cm} (67)

Let $U_k$ denote the subtask that misses its deadline at $t_d$. Because $d(U_k) = t_d$ and $U$ is not scheduled at $t_d - 1$ (by part e), the deadline of every subtask scheduled at $t_d - 1$ is equal to $t_d$. (It is not less than $t_d$, by part (d).) Let $V_l$ be a subtask in $T$.

By Lemma 1, and because $wt(V) < 1$ holds, $|w(V_l)| \geq 2$ holds. This implies that the release time of $V_l$, and in general, the release time of each subtask in $T$ is at or before $t_d - 2$, as shown in Fig. 10.

Thus, by (66), at least $M - N_1$ subtasks scheduled at $t_d - 1$ have their release times at or before $t_d - 2$. By (63), at every time slot at least $M - N_1$ processors are available for scheduling tasks in $\tau_1$. Therefore, the fact that no subtask in $T$ is scheduled at $t_d - 2$ implies that for every subtask $V_l$ in $T$, some other subtask of a task in $\tau - \tau_1$ (which could be $V_l$'s predecessor) is scheduled at $t_d - 2$, i.e., we have the following.

(P1) At least $M - N_1$ tasks in $\tau - \tau_1$ are scheduled at $t_d - 2$. 

26
Let $h \geq 0$ denote the number of holes in slot $t_d - 2$. Then, by (P1), it implies that at most $M - (M - N_1) - h = N_1 - h$ tasks in $\tau_1$ are scheduled at $t_d - 2$, i.e.,

$$\sum_{T \in \tau_1} S(T, t_d - 2) \overset{\text{def}}{=} N_1^s \leq N_1 - h.$$  \hspace{1cm} \text{(68)}

Let $\tau_1^2$ denote the subset of all tasks in $\tau_1$ that are not scheduled at $t_d - 2$. If $h > 0$ holds, then $\tau_1^2 \neq \emptyset$ holds, and let $Y$ be a task in $\tau_1^2$. By Lemma 18, there exists a time $u \leq t_d - 2$ such that $Y$ is a $Z$-task at $u$ and there are no holes in any slot in $[u, t_d - 2)$. Define $v$ as follows.

$$v \overset{\text{def}}{=} \begin{cases} t_d - 2, & \tau_1^2 = \emptyset \\ \min_{Y \in \tau_1^2} \{u \leq t_d - 2: \text{there are no holes in } [u, t_d - 2) \text{ and } Y \text{ is a } Z\text{-task in at least one slot in } [u, t_d - 1)\} & \tau_1^2 \neq \emptyset \end{cases}$$

$v$ satisfies the following.

Every task in $\tau_1^2$ is a $Z$-task in at least one slot in the interval $[v, t_d - 1)$. \hspace{1cm} \text{(69)}

There are no holes in $[v, t_d - 2)$. \hspace{1cm} \text{(70)}

To complete the proof, we are left with determining a lower bound on $\text{LAG}(\tau, v)$. By (21), we have

$$\text{LAG}(\tau, v) = \text{LAG}(\tau, t_d) - \sum_{T \in \tau} \sum_{u=v}^{t_d-1}(\text{share}(T, u) - S(T, u))$$

$$= 1 - \sum_{T \in \tau} \sum_{u=v}^{t_d-1}(\text{share}(T, u) - S(T, u)),$$

$$= 1 - \sum_{T \in \tau} \sum_{u=v}^{t_d-1}\text{share}(T, u) + \sum_{T \in \tau} \sum_{u=v}^{t_d-1}S(T, u)$$

$$= 1 - (\sum_{T \in \tau} \sum_{u=v}^{t_d-1}\text{share}(T, u) = (t_d - v)M - h)$$

, there are $h$ holes in $t_d - 2$; by part (f), there are no holes in $t_d - 1$, and by (70), there are no holes in $[v, t_d - 2)$

$$= 1 - \sum_{T \in \tau_1} \sum_{u=v}^{t_d-2}\text{share}(T, u) - \sum_{T \in \tau - \tau_1} \sum_{u=v}^{t_d-2}\text{share}(T, u) - \sum_{T \in \tau} \text{share}(T, t_d - 1) + (t_d - v)M - h$$

$$\geq 1 - \sum_{T \in \tau_1} \sum_{u=v}^{t_d-2}\text{share}(T, u) - \sum_{T \in \tau - \tau_1} \sum_{u=v}^{t_d-2} \text{wt}(T) - \sum_{T \in \tau} \text{wt}(T) + (t_d - v)M - h$$

, by (17)

$$= 1 - \sum_{T \in \tau_1} \sum_{u=v}^{t_d-2}\text{share}(T, u) - (\alpha M - N_1)(t_d - v - 1) - \alpha M + (t_d - v)M - h$$

, by (65) and Def. 6

$$= 1 - \sum_{T \in (\tau_1 - \tau_1^2)} \sum_{u=v}^{t_d-2}\text{share}(T, u) - \sum_{T \in \tau_1^2} \sum_{u=v}^{t_d-2}\text{share}(T, u)$$

$$= (\alpha M - N_1)(t_d - v - 1) - \alpha M + (t_d - v)M - h$$

$$\geq 1 - \sum_{T \in (\tau_1 - \tau_1^2)} \sum_{u=v}^{t_d-2}\text{wt}(T) - \sum_{T \in \tau_1^2} \sum_{u=v}^{t_d-2}\text{share}(T, u)$$

$$= (\alpha M - N_1)(t_d - v - 1) - \alpha M + (t_d - v)M - h$$

, by (17)

$$= 1 - (N_1^2)(t_d - v - 1) - \sum_{T \in \tau_1^2} \sum_{u=v}^{t_d-2}\text{share}(T, u) - (\alpha M - N_1)(t_d - v - 1) - \alpha M + (t_d - v)M - h$$

, by Def. 8 and (14)

$$\geq 1 - \sum_{T \in \tau_1^2} \sum_{u=v}^{t_d-2} \text{wt}(T)$$

, by (68), and the definitions of $\tau_1$ and $\tau_1^2$
Further,\[ -(N_2^*)(t_d - v - 1) - (\alpha M - N_1^*)(t_d - v - 1) - \alpha M + (t_d - v)M - h,\] by (17)
\[ \geq 1 - \sum_{T \in \tau_1^*} (t_d - v - 2)wt(T)\]
\[ -(N_2^*)(t_d - v - 1) - (\alpha M - N_1^*)(t_d - v - 1) - \alpha M + (t_d - v)M - h,\] by (69)
\[ = 1 - (N_1 - N_2^*)(t_d - v - 2)\]
\[ -(N_1^*)(t_d - v - 1) - (\alpha M - N_1^*)(t_d - v - 1) - \alpha M + (t_d - v)M - h,\]
\[ = 1 + N_1 - N_1^* - \alpha M(t_d - v) + M(t_d - v) - h,\]
\[ \geq 1 + h - \alpha M(t_d - v) + M(t_d - v) - h,\] by (68)
\[ = 1 + (M - \alpha M)(t_d - v).\]

**Proof of (h):** Follows from the facts that $LAG(\tau, 0) = 0$ and there exists a $v \leq t_d - 2$ such that $LAG(\tau, v) \geq (t_d - v)(1 - \alpha)M + 1$ (from part (g)). Note that, by Lemma 4, $(t_d - v)(1 - \alpha)M + 1 \geq 1$.

**Lemma 19** \[ \frac{(k(k-1)M+1)((k-1)W_{\max}+k)-1}{Mk^2(k-1)(1+W_{\max})} < 1,\] where $k = \left\lfloor \frac{1}{W_{\max}} \right\rfloor + 1$, for all $0 < W_{\max} \leq 1$, $M > 1$.

**Proof:** Because $k = \left\lfloor \frac{1}{W_{\max}} \right\rfloor + 1$ (by the statement of the lemma), we have
\[ k = \left\lfloor \frac{1}{W_{\max}} \right\rfloor + 1 > \frac{1}{W_{\max}} \]
\[ \Leftrightarrow W_{\max} > \frac{1}{k} \] (71)

Further,
\[ \frac{(k(k-1)M+1)((k-1)W_{\max}+k)-1}{Mk^2(k-1)(1+W_{\max})} = \frac{Mk^2(k-1)(W_{\max}+1) + (k-1)(W_{\max}+1 - MkW_{\max})}{Mk^2(k-1)(W_{\max}+1)} .\]

By (71), $W_{\max} + 1 - MkW_{\max} < W_{\max} + 1 - M$ holds. Because $W_{\max} + 1 - M \leq 0$ holds for all $M > 1, W_{\max} + 1 - MkW_{\max} < 0$ holds. Because $k \geq 2$ holds, we have $(k-1)(W_{\max}+1-MkW_{\max}) < 0$, and hence,
\[ \frac{Mk^2(k-1)(W_{\max}+1) + (k-1)(W_{\max}+1 - MkW_{\max})}{Mk^2(k-1)(W_{\max}+1)} < 1 \] holds.

**Lemma 20** A solution to the recurrence
\[ L_0 < \delta + \delta \cdot \alpha M, \]
\[ L_k \leq \delta \cdot L_{k-1} + \delta \cdot (2\alpha M - M), \] (72)

where $0 \leq \delta < 1$, is given by
\[ L_k < \delta^{k+1}(1 + \alpha M) + (1 - \delta^k)\left( \frac{\delta}{1 - \delta} \right)(2\alpha M - M), \quad \text{for all } k \geq 0. \] (73)
Proof: The proof is by induction on \( k \).

Base Case: Holds for \( k = 0 \).

Induction Hypothesis: Assume that (73) holds for \( L_0, \ldots, L_k \).

Induction Step: Using (72), we have

\[
L_{k+1} \leq \delta L_k + \delta(2\alpha M - M)
\]

\[
< \delta^{k+2}(1 + \alpha M) + \delta(1 - \delta^k) \left( \frac{\delta}{1 - \delta} \right) (2\alpha M - M) + \delta(2\alpha M - M) \quad \text{by (73) (induction hypothesis)}
\]

\[
= \delta^{k+2}(1 + \alpha M) + \delta(2\alpha M - M)((1 - \delta^k) \left( \frac{\delta}{1 - \delta} \right) + 1)
\]

\[
= \delta^{k+2}(1 + \alpha M) + (1 - \delta^{k+1}) \left( \frac{\delta}{1 - \delta} \right) (2\alpha M - M),
\]

which proves the lemma. \( \square \)

Lemma 21 \( \frac{M(2 - \delta - \delta^{n+1}) + \delta^{n+2} - \delta^{n+1} + 1 - \delta}{M(2 - \delta - \delta^{n+1} - \delta^{n+2})} \geq \frac{M(2 - \delta) + \frac{1}{2}}{2M} \) holds for all \( n \geq 0, 0 \leq \delta \leq 1/2 \), and \( M \geq 1 \).

Proof: Because

\[
\frac{M(2 - \delta - \delta^{n+1}) + \delta^{n+2} - \delta^{n+1} + 1 - \delta}{M(2 - \delta - \delta^{n+1} - \delta^{n+2})} \geq \frac{M(2 - \delta) + \frac{1}{2}}{2M}
\]

\[
\Leftrightarrow 5\delta^{n+2} - 3\delta^{n+1} + 2M\delta^{n+2}(1 - \delta) + 2 - 4\delta \geq 0 \quad \text{, simplifying}
\]

\[
\Leftrightarrow 5\delta^{n+2} - 3\delta^{n+1} + 2\delta^{n+2}(1 - \delta) + 2 - 4\delta \geq 0 \quad \text{, because } M \geq 1 \text{ and } 0 \leq \delta \leq 1/2
\]

\[
\Leftrightarrow -2\delta^{n+3} + 7\delta^{n+2} - 3\delta^{n+1} - 4\delta + 2 \geq 0,
\]

it suffices to show that \( h(\delta) \overset{\text{def}}{=} -2\delta^{n+3} + 7\delta^{n+2} - 3\delta^{n+1} - 4\delta + 2 \geq 0 \), for \( 0 \leq \delta \leq 1/2 \) and \( n \geq 0 \). Because \( h(\delta) = -(2\delta - 1)(\delta^{n+1}(\delta - 3) + 2) \), and \( -(2\delta - 1) \geq 0 \), it suffices to show that \( g(\delta) \overset{\text{def}}{=} \delta^{n+1}(\delta - 3) + 2 \) is at least zero.

The first derivative of \( g(\delta) \) is given by \( g'(\delta) = \delta^n((n + 2)\delta - 3(n + 1)) \). The roots of \( g'(\delta) \) are \( \delta = 0 \) and \( \delta = \frac{3(n+1)}{n+2} \).

\[
\frac{3(n+1)}{n+2} \geq \frac{3}{2} \text{ holds for all } n \geq 0.
\]

Therefore, \( g(\delta) \) is either increasing or decreasing in \([0, \frac{1}{2}]\). \( g(0) = 2 \) and \( g(\frac{1}{2}) \) lies in \([\frac{3}{4}, 2]\) for all \( n \geq 0 \). Therefore, \( g(\delta) \) is positive in \([0, \frac{1}{2}]\), and hence, \( h(\delta) \geq 0 \) in that interval. \( \square \)
